Executive Summary

Content

The City of Brantford is undertaking a Class Environmental Assessment (EA) for streetscaping the Downtown to improve walkability, accessibility, and underground infrastructure to allow for development, enhance the infrastructure for all transportation modes, and increase pedestrian capacity. The goal of the streetscaping improvements is to create a Downtown that is attractive, vibrant and safe for users and provides the infrastructure needed to accommodate expected growth.

This supporting Transportation Study examines the proposed streetscaping alternatives from multi-modal, safety and traffic operations perspective.

The multi-modal study approach included:

- An examination of the existing road network, traffic, land use and travel characteristics along Colborne Street and Dalhousie Street to illustrate the transportation context for the corridors;
- A road safety performance assessment and recommended mitigation measures based on collision history, field investigation and predictive safety techniques;
- Forecast 2025, 2030 and 2051 traffic patterns and operational analyses to identify deficiencies in the existing road network;
- Traffic operations assessments for the improvement alternatives to determine the merits in; and
- Evaluation of the candidate solutions in terms of their ability to maintain satisfactory traffic operations while capitalizing on the walkability, pedestrian capacity and active transportation within the downtown.

Five alternatives were considered:

- **Alternative 1: Do-Nothing:** Current configurations along Colborne Street and Dalhousie Street; one-way operation with on-street parking permitted through various segments. Sidewalks are provided on both sides of the roadway with a reduced public realm. Additionally, there are no cycling facilities provided within the study area.
- **Alternative 2: Two Way (Bi-Directional Cycle)**: Consists of providing two-way traffic flow on Colborne Street and Dalhousie Street while providing a dedicated bi-directional cycling facility on one-side of the roadway. On-street parking will be dedicated

to one-side of the street providing for narrow travel lanes to reduce speed however pedestrian space is not any wider than existing.

- **Alternative 3: Two Way (Separated Cycle)**: Consists of providing two-way traffic flow on Colborne Street and Dalhousie Street while providing a dedicated cycling facility on both sides of the roadway. On-street parking will be dedicated to one-side of the street providing for narrow travel lanes to reduce speed however pedestrian space is not any wider than existing.
- **Alternative 4: One Way (Bi-Directional Cycle)**: Maintains one-way traffic flow on Colborne Street and Dalhousie Street while providing a dedicated bi-directional cycling facility on one side of the roadway. On-street parking will be dedicated to one side of the street, providing for narrow travel lanes to reduce speed; however, pedestrian space is not any wider than existing.
- **Alternative 5: One Way (Separated Single Cycle)**: Maintains one-way traffic flow on Colborne Street and Dalhousie Street while providing a dedicated cycling facility on one side of the roadway. On-street parking will be dedicated to one side of the street, providing narrow travel lanes to reduce speed and additional space, increasing pedestrian space.

A preliminary evaluation of the alternatives by the study team concluded that Do-Nothing would not be carried forward as it did not capitalize on the walkability, pedestrian capacity and active transportation within the downtown. As a result, the report primarily focused on Alternative 2-5.

Conclusions

Colborne Street and Dalhousie Street has frequently been discussed as a potential street to convert from one-way to two-way. Decisions regarding one-way versus two-way streets need to be context sensitive and value-based, having regard for the shared community vision, planned road functions, and competing interests for the valued and often constrained right-of-way (ROW) of any given street.

Operations

The 2051 forecast traffic conditions under the one-way and two-way scenarios indicate that the peak period level of service conditions at the downtown street intersections are generally satisfactory. This is particularly the case within the downtown area, where most intersections operate at a level of service A or B. The intersections projected to experience some congestion are generally at the centre of the downtown core (i.e., Clarence Street) under both the one-way and two-way scenarios.

A widening of Clarence Street would result in significant property impacts and would be constrained by the railway spur line on the east side (limiting widening options to the west side). The Veterans Memorial Parkway partial extension (to Murray Street) provides an opportunity for an alternative route out of downtown via Murray Street. A partial extension of the Veterans Memorial Parkway could be considered beyond 2051 to address potential long-term issues and should be protected for as an alternative to Clarence Street.

In addition, the two-way scenario is also expected to create some additional capacity constraints at the intersection of Colborne Steet and Brant Avenue given modifications to the east leg are required to achieve a straight alignment through the intersection.

In summary, the one-way scenario offers the least amount of delay and travel time as a result of limited conflicts for turning vehicles at intersections as there is no traffic travelling in the opposite direction to delay either a left turn or right turn movement.

Complete Street

As the primary intent of the preferred streetscaping alternative is to improve walkability and accessibility for all transportation modes, one of the main objectives in determining the preferred alternative is to create a complete street. Although it seems to be a commonly held view that converting the high-speed and high-capacity one-way downtown streets to two-way could be necessary for a downtown revitalization program, there are advantages to bringing together different types of activities within a relatively dense and diversified environment. There are also advantages to using multitudinous strategies to achieve an objective with several interrelated factors.

As the downtown streets are provided with a narrow right-of-way with limited opportunity to expand, there are many competing interests for space, including sidewalks, bus stops/shelters, landscaping, public art, bicycle parking, vendor boxes, streetlights, fire hydrants, on-street parking, and travel lanes. Given the intensity of use and the increase in intensity envisioned with the Streetscape investment, decisions regarding space allocation are anticipated to become more complex.

Balancing the competing interests for space is always the first challenge when designing complete streets. In downtown Brantford, this competition is fierce due to the volume of travel in all modes that must be accommodated within municipal street rights-of-way that are incredibly narrow. As a result, it is sensible to create street design solutions that can fit within the narrow right-of-way that covers most of downtown Brantford.

Pedestrian Safety

Pedestrian safety in downtown commercial streets is paramount because in most cases, a downtown motorist's destination is some place to park the car, namely a garage, lot or on-street parking space; upon parking, the motorist leaves the vehicle as a pedestrian to access the final destination.

Both sides of the one-way to two-way debate accept the importance of pedestrian safety but there is not an agreement as to which way of travel is actually safer as pedestrian safety may depend on characteristics that can only be determined on a case-by-case basis. There are several benefits of two-way streets that positively affect pedestrian safety and pedestrian experience; a relatively new criterion for successful downtowns.

Preferred Arrangement

The foregoing assessment indicates there are valid arguments for both maintaining an existing one-way street network in Downtown Brantford, and conversely, converting one-way operation to two-way operation.

In downtown Brantford's case, the primary one-way street network is considered somewhat unique given the connectivity the subject streets provide to critical elements of the region's transportation infrastructure and bridge crossings of rivers. It is also worth noting that the downtown streets with the most mixed and street-oriented land use and high and sustained pedestrian activity are two-way streets. More importantly, the narrow ROW reality of downtown Brantford streets creates added pressure on the roads to operate as efficiently as possible for all modes. Since the vision for the downtown is to pursue avenues that can provide wider sidewalks and on-street cycling facilities, as well as basic functionality for vehicles and buses, this tends to balance the scales towards one-way operation, provided the narrow ROW can be re-arranged accordingly.

Preferred Alternative

As the one-way operation is seen as the beneficial arrangement in meeting the overall goals and intent of the Streetscaping alternative, Alternatives 4 and 5 were determined to meet this criteria for further consideration. A comparison of these alternative concluded that Alternative 5 is preferred over Alternative 4 as it is better suited towards improving road safety and enhancing the overall pedestrian realm.

To ensure that the response times of emergency vehicles are not impacted negatively by the proposed changes to Colborne Street and

Dalhousie Street, it is recommended that City of Brantford Transportation Services work with Brantford Fire Services to further refine the pre-emption along the Colborne Street and Dalhousie Street corridor. In addition, further consultation with Brantford Fire Services is recommended during detailed design.

To improve the potential safety hazards within the sub study-area, the implementation of a blanket 40 kilometres posted speed limit along Colborne Street and Dalhousie Street is preferred. Furthermore, improved sidewalks (i.e., wider with limited to no obstructions) and cycling facilities will need to be incorporated. Ultimately, the preferred design and streetscape design should support these recommendations.

Other improvements that may need to be considered in the final design could include bike signals, pedestrian only phases (reserved for intersections with high pedestrian volumes) and pedestrian leading green time to provide pedestrians with an advance opportunity to cross before vehicles are allowed to proceed right.

Additionally, the measures identified are further recommended for consideration:

- The intersection of Dalhousie Street and Bridge Street be modified to only one-way traffic in the northbound direction to reduce the number of potential conflicts with westbound through traffic.
- To mitigate the number of active transportation collisions along Colborne Street between the Market Street IPS and Clarence Street, an additional controlled crossing be considered.

1 Introduction

The City of Brantford retained MTE Consultants Inc. to undertake a Municipal Class Environmental Assessment (EA) study for streetscaping the downtown core. The project's goal is, in part, to create an aesthetically beautiful environment boosting the image and awareness of the downtown revitalization efforts. The main objectives are to create a complete street that will enhance the walkability and pedestrian capacity downtown, to animate these streets and to become a place-making destination.

This Transportation and Traffic Analysis Report is a supporting technical report for the Class EA.

1.1 Study Purpose and Scope

Paradigm Transportation Solutions Limited (Paradigm) as a member of the MTE Consultants Inc. team has carried out a sub-area transportation network analysis in support of the Municipal Class EA Study. This Transportation and Traffic Analysis Report assesses existing traffic conditions and deficiencies and determines the transportation demands and the associated network improvements required for the horizon years of 2025, 2030 and 2051.

The detailed transportation and traffic analysis examines the streetscape implementation of Colborne Street and Dalhousie Street to improve active transportation, walkability, pedestrian capacity and to confirm the appropriate configuration of the improvements.

1.2 Study Area

The study area includes Colborne Street and Dalhousie Street from the junction, extending to Brant Avenue and Icomm Drive. It also captures the connecting north/south streets between this area including Brant Avenue, King Street, Queen Street, Market Street, Charlotte Street, and Clarence Street. **Figure 1.1** illustrates the study area.

paradigm TRANSPORTATION SOLUTIONS LIMITED

Study Area

1.3 Proposed Alternatives

As part of the downtown revitalization efforts, the City of Brantford's preferred alternative will capitalize on the walkability, pedestrian capacity and active transportation in the downtown. To realize this goal, several alternative cross-sections for both Colborne Street and Dalhousie Street have been developed:

- **Alternative 1: Do-Nothing:** Current configurations along Colborne Street and Dalhousie Street; one-way operation with on-street parking permitted through various segments. Sidewalks are provided on both sides of the roadway with a reduced public realm. Additionally, there are no cycling facilities provided within the study area.
- **Alternative 2: Two Way (Bi-Directional Cycle)**: Consists of providing two-way traffic flow on Colborne Street and Dalhousie Street while providing a dedicated bi-directional cycling facility on one-side of the roadway. On-street parking will be dedicated to one-side of the street providing for narrow travel lanes to reduce speed however pedestrian space is not any wider than existing.
- **Alternative 3: Two Way (Separated Cycle)**: Consists of providing two-way traffic flow on Colborne Street and Dalhousie Street while providing a dedicated cycling facility on both sides of the roadway. On-street parking will be dedicated to one-side of the street providing for narrow travel lanes to reduce speed however pedestrian space is not any wider than existing.
- **Alternative 4: One Way (Bi-Directional Cycle)**: Maintains one-way traffic flow on Colborne Street and Dalhousie Street while providing a dedicated bi-directional cycling facility on one-side of the roadway. On-street parking will be dedicated to one-side of the street providing for narrow travel lanes to reduce speed however pedestrian space is not any wider than existing.
- **Alternative 5: One Way (Separated Single Cycle)**: Maintains one-way traffic flow on Colborne Street and Dalhousie Street while providing a dedicated cycling facility on one side of the roadway. On-street parking will be dedicated to one side of the street, providing narrow travel lanes to reduce speed and gain additional space to increase the pedestrian realm.

The study team concluded that Alternative 1: Do-Nothing, did not meet a significant number of the criteria and through the EA screening process would not be carried forward. **Figure 1.2** illustrates this process.

2.1 Study Area Network

Colborne Street is a one-way street providing traffic flow in the easterly direction through the Downtown. This roadway forms the southerly section of the designated arterial road through the Downtown area. It has a three lane-cross section within the study area with turning lanes provided at strategic locations. The roadway has a posted speed limit of 50 kilometres per hour. Parking is permitted on both sides of the road through various segments of the corridor, contained mainly to on-street parking bays.

Dalhousie Street is a one-way street providing traffic flow in the westerly direction through the Downtown. This roadway forms the northern section of the designated arterial road through the Downtown area. It has a three lane-cross section within the study area with turning lanes provided at strategic locations. The roadway has a posted speed limit of 50 kilometres per hour. Parking is permitted on both sides of the road through various segments of the corridor, contained mainly to on-street parking bays.

Within the study area, the following collector and local roads intersect Colborne Street and Dalhousie Street and form the basis for the transportation network analysis:

- **Brant Avenue** is a north-south, four-lane, minor arterial roadway with an urban cross-section. The maximum posted speed limit is 50 km/h. South of Colborne Street West, Brant Avenue operates south with a four-lane, undivided cross-section, with two travel lanes per direction. Parking is not permitted on either side of the road.
- **King Street** is a north-south, minor arterial that operates with a two-lane cross-section. The posted maximum speed limit is 50 km/h. Parking is permitted on both sides of the road between Colborne Street and Darling Street.
- **Queen Street** is a north-south, minor arterial that operates with a two-lane cross-section. The posted maximum speed limit is 50 km/h. Parking is permitted on both sides of the road between Dalhousie Street and Darling Street.
- **Market Street** is a north-south, major collector that operates with a two-lane cross-section. The posted maximum speed limit is 50 km/h. Parking is permitted on both sides of the road within the study area.

- **Charlotte Street** is a north-south, local roadway that operates with a two-lane cross-section. The posted maximum speed limit is 50 km/h. Parking is permitted on both sides of the road between Colborne Street and Dalhousie Street and limited to the west side north of Dalhousie Street.
- **Clarence Street** is a major arterial that operates with a four-lane cross-section. The posted maximum speed limit is 50 km/h. Parking is prohibited on both sides of the road.

Table 2.1 provides a summary of major road characteristics within the study rea.

TABLE 2.1: ROAD CHARACTERISTICS WITH STUDY AREA

Road	Speed Limit	Classification	Cross-Section	Land Uses Serviced
Colborne Street	50	Major Arterial	3-Lanes	Core Commercial
Dalhousie Street	50	Major Arterial	3-Lanes	Core Commercial
Brant Avenue	50	Major Arterial	4-Lanes	Core Commercial
King Street	50	Minor Arterial	2-Lanes	Core Commercial
Queen Street	50	Minor Arterial	2-Lanes	Core Commercial
Market Street	50	Major Collector	2-Lanes	Core Commercial
Charlotte Street	50	Local	2-Lanes	Core Commercial
Clarence Street	50	Major Arterial	4-Lanes	Core Commercial

2.3 Traffic Demand

Turning movement counts (TMC) quantify the volume, and type of vehicles travelling through an intersection. The TMC data is typically collected during peak travel periods to capture peak traffic volumes and patterns.

In March 2020, the Provincial and Federal governments enacted measures to reduce the spread of COVID-19. Provincial measures included the closure of non-essential businesses and schools. Federal measures included the closure of the International Border to the United States of America, except for essential travel.

As a result of the COVID-19 pandemic, the ability to collect new traffic count data was not feasible at the commencement of the study given the irregular traffic volumes that would be present. However, there are a number of tools and methods we can rely on to develop reasonable traffic demand projections for the study area roadways based on historical count data available. **Table 2.2** summarizes the historical traffic date of each the study area intersections. **Appendix A** includes the traffic data.

TABLE 2.2: SUMMARY OF TRAFFIC DATA

Intersection	Date
Dalhousie Street at Brant Avenue	December 2012 June 2008
Dalhousie Street at King Street	February 2014 November 2007
Dalhousie Street at Queen Street	July 2018 November 2007
Dalhousie Street at Market Street	August 2014
Dalhousie Street at Charlotte Street	March 2006
Dalhousie Street at Clarence Street	November 2007
Colborne Street at Brant Avenue	June 2008
Colborne Street at King Street	November 2007
Colborne Street at Queen Street	October 2015
Colborne Street at Charlotte Street	November 2007
Colborne Street at Market Street (walkway)	June 2012 June 2005
Colborne Street at Clarence Street	November 2018 November 2007
Colborne Street at Dalhousie Street	March 2015

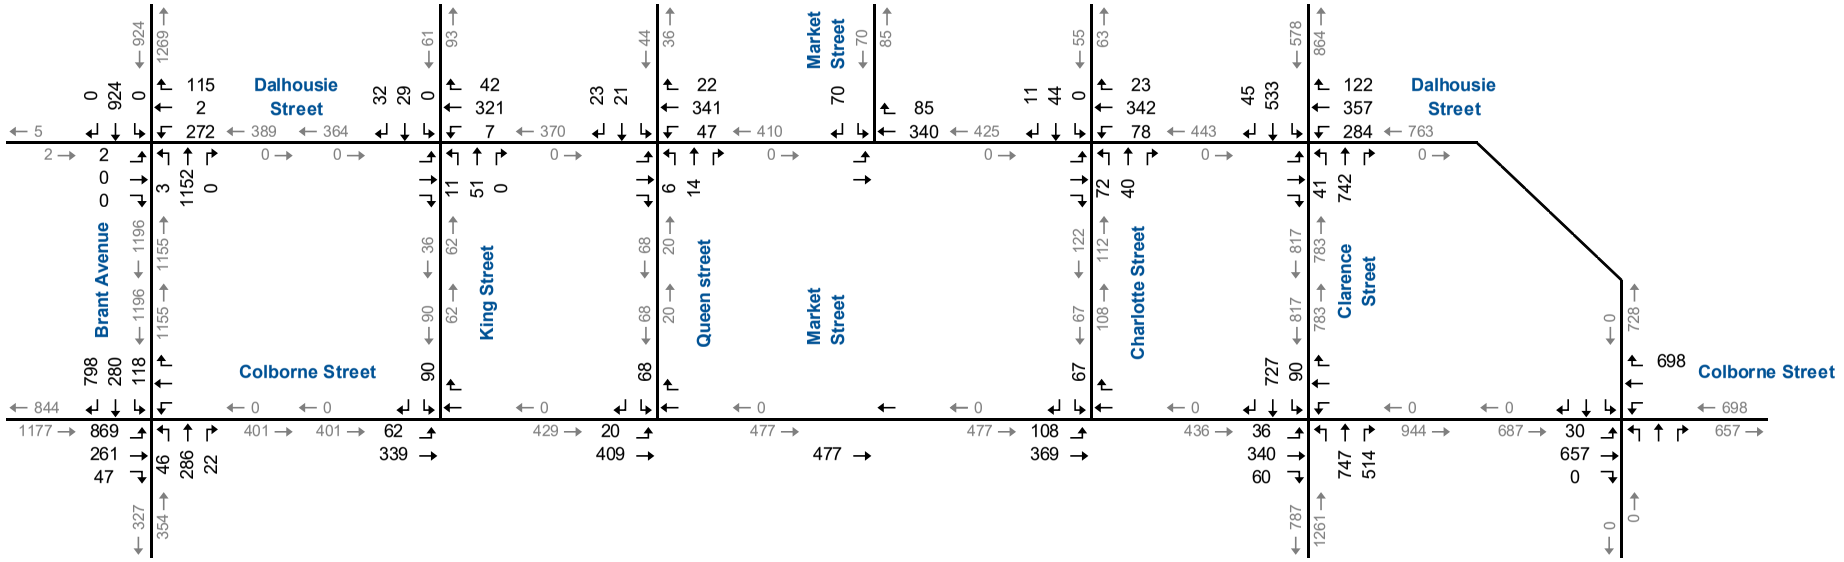
Reasonable demand projections can also be produced through the use of historical data. As the corridors of Colborne Street and Dalhousie Street have a number of intersections within historical count data, a regression analysis has been completed to determine the growth level. Based on the historical volume comparison, the following is noted:

- No significant growth is occurring along Colborne Street and Dalhousie Street, actually a decrease is occurring. Growth if any, is occurring for the minor approaches (north/south movements) however is marginal and likely be representative of 1% per annum.
- Significant growth is occurring along Brant Avenue and likely be representative of 3% per annum.

As the analysis for this study has a primary focus on major signalized intersections, it is noted that unsignalized intersections, driveways, etc., in between major signalized intersections would account for discrepancies between traffic volumes. In addition, the data for each intersection may have been collected at different times and dates, which would also account for discrepancies between the adjacent volumes.

As a result of these discrepancies, volume balancing has been undertaken to ensure there were no irregularities between the upstream and downstream volumes along the respective corridors. Exception to this is segments that contained a driveway/intersection that would be a primary origin/destination for users within the defined study area (i.e., public parking lot/garage).

Figure 2.2 illustrates the intersection turning movement volumes within the study area for the weekday peak hours.



Adjusted Base Year
PM Peak Hour Traffic Volumes

Downtown Brantford Streetscape Class EA – Transportation Study
190449

Figure 2.2B

Figure 2.3 illustrate a summary of the peak hour traffic volumes along Colborne Street and Dalhousie Street by major road segments relative to the estimated roadway capacity for the weekday peak hours. It is noted that the roadway capacity as provided in the City's EMME model has been utilized.

Peak hour peak direction traffic volumes on Colborne Street are approximately 400 to 670 vehicles per hour (veh/hr) between Brant Avenue and Charlotte Street. Segments to the east of Clarence Street are noted to be 1,000 veh/hr. Daily traffic volumes along Colborne Street within the study area reaches about 10,000 vehicles per day which is at the lower end of typical flow characteristic of a major arterial as per the Transportation Association of Canada (TAC) guidelines[1].

Peak hour peak direction traffic volumes on Dalhousie Street are approximately 400 to 800 vehicles per hour (veh/hr) between Brant Avenue and Charlotte Street. Segments to the east of Clarence Street are noted to be 1,000 veh/hr. Daily traffic volumes along Colborne Street within the study area reaches about 10,000 vehicles per day which is at the lower end of typical flow characteristic of a major arterial as per the Transportation Association of Canada (TAC) guidelines.

paradigm TRANSPORTATION SOLUTIONS LIMITED

Base Year Capacity Comparison

2.4 Transit

The City of Brantford has a well-developed public transit service operated by Brantford Transit. This service provides conventional public transit services throughout the urban area of Brantford.

The central focus of the City of Brantford transit services is the off-street “transit hub” on the north side of Darling Street and west of Market Street. This terminal provides a downtown route terminus for the various bus routes, with an off-street stop for each route and sheltered passenger waiting areas.

Almost all of the public transit services connect to the downtown transit terminal, operating along the streets within the downtown area. The primary streets used are Colborne Street, Dalhousie Street, Market Street, Clarence Street, Darling Street, Wellington Street, and Brant Avenue. Buses typically operate every 30 minutes on weekdays, with service every 30 minutes during the day on Saturdays and every 60 minutes during evening and Sunday periods.

Figure 2.4 provides an overview of the bus routes and bus stops within the downtown area.

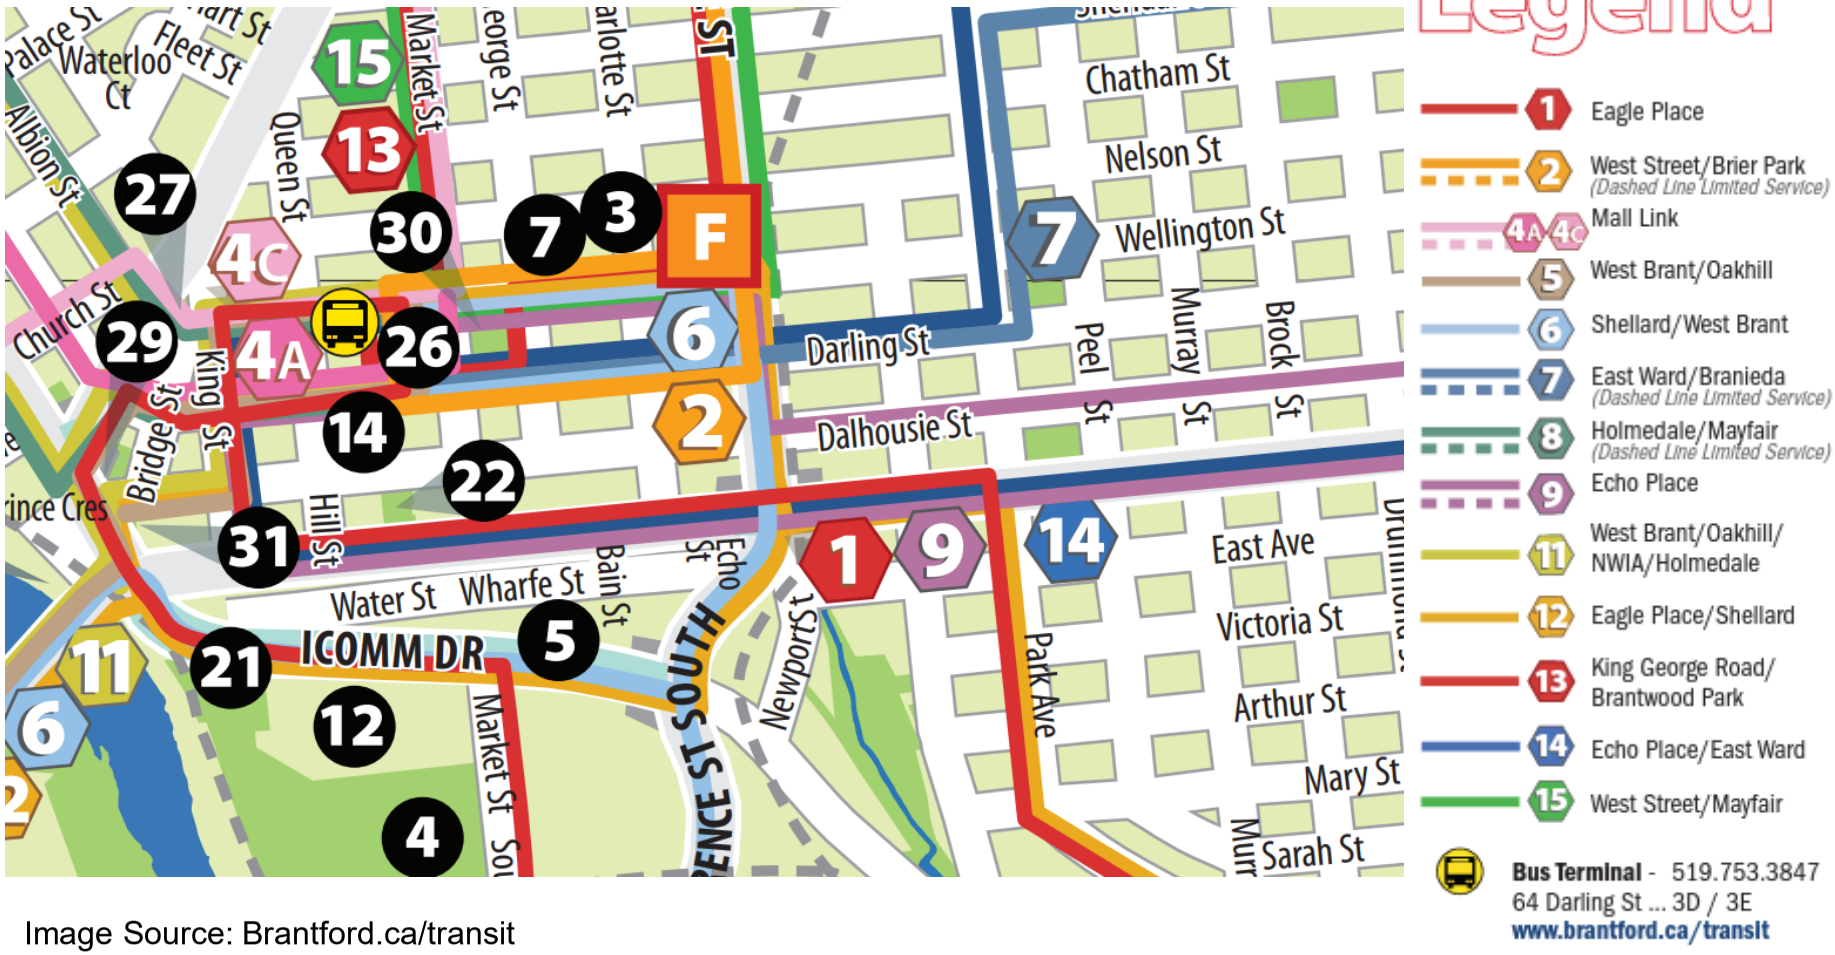

Image Source: Brantford.ca/transit

paradigm TRANSPORTATION SOLUTIONS LIMITED

Existing Transit Network

2.5 Active Transportation

2.5.1 Pedestrians

Along the corridor, pedestrians use sidewalks that are provided on both sides of the study area roadways. During the site visit, Paradigm performed spot measurements along each sidewalk corridor. Average sidewalk widths varied between 3.0 metres on the majority of the sidewalks with increased width of up to 5.0 metres at the western limits of the study area along Colborne Street and Dalhousie Street.

All signalized intersections include pedestrian push buttons, pedestrian signal heads, and delineated crosswalks. However, the channelized southbound right-turn movement on Brant Avenue at Colborne Street West consists of an uncontrolled pedestrian crossing.

There is generally a high level of pedestrian activity within the downtown area. The relative levels of pedestrian activity at each intersection are illustrated in **Figure 2.5**.

The highest pedestrian volumes were observed centrally within the study area along Queen Street and Market Street with Colborne Street and Dalhousie Street. Intersections towards the east and west of the downtown have notably lower pedestrian volumes.

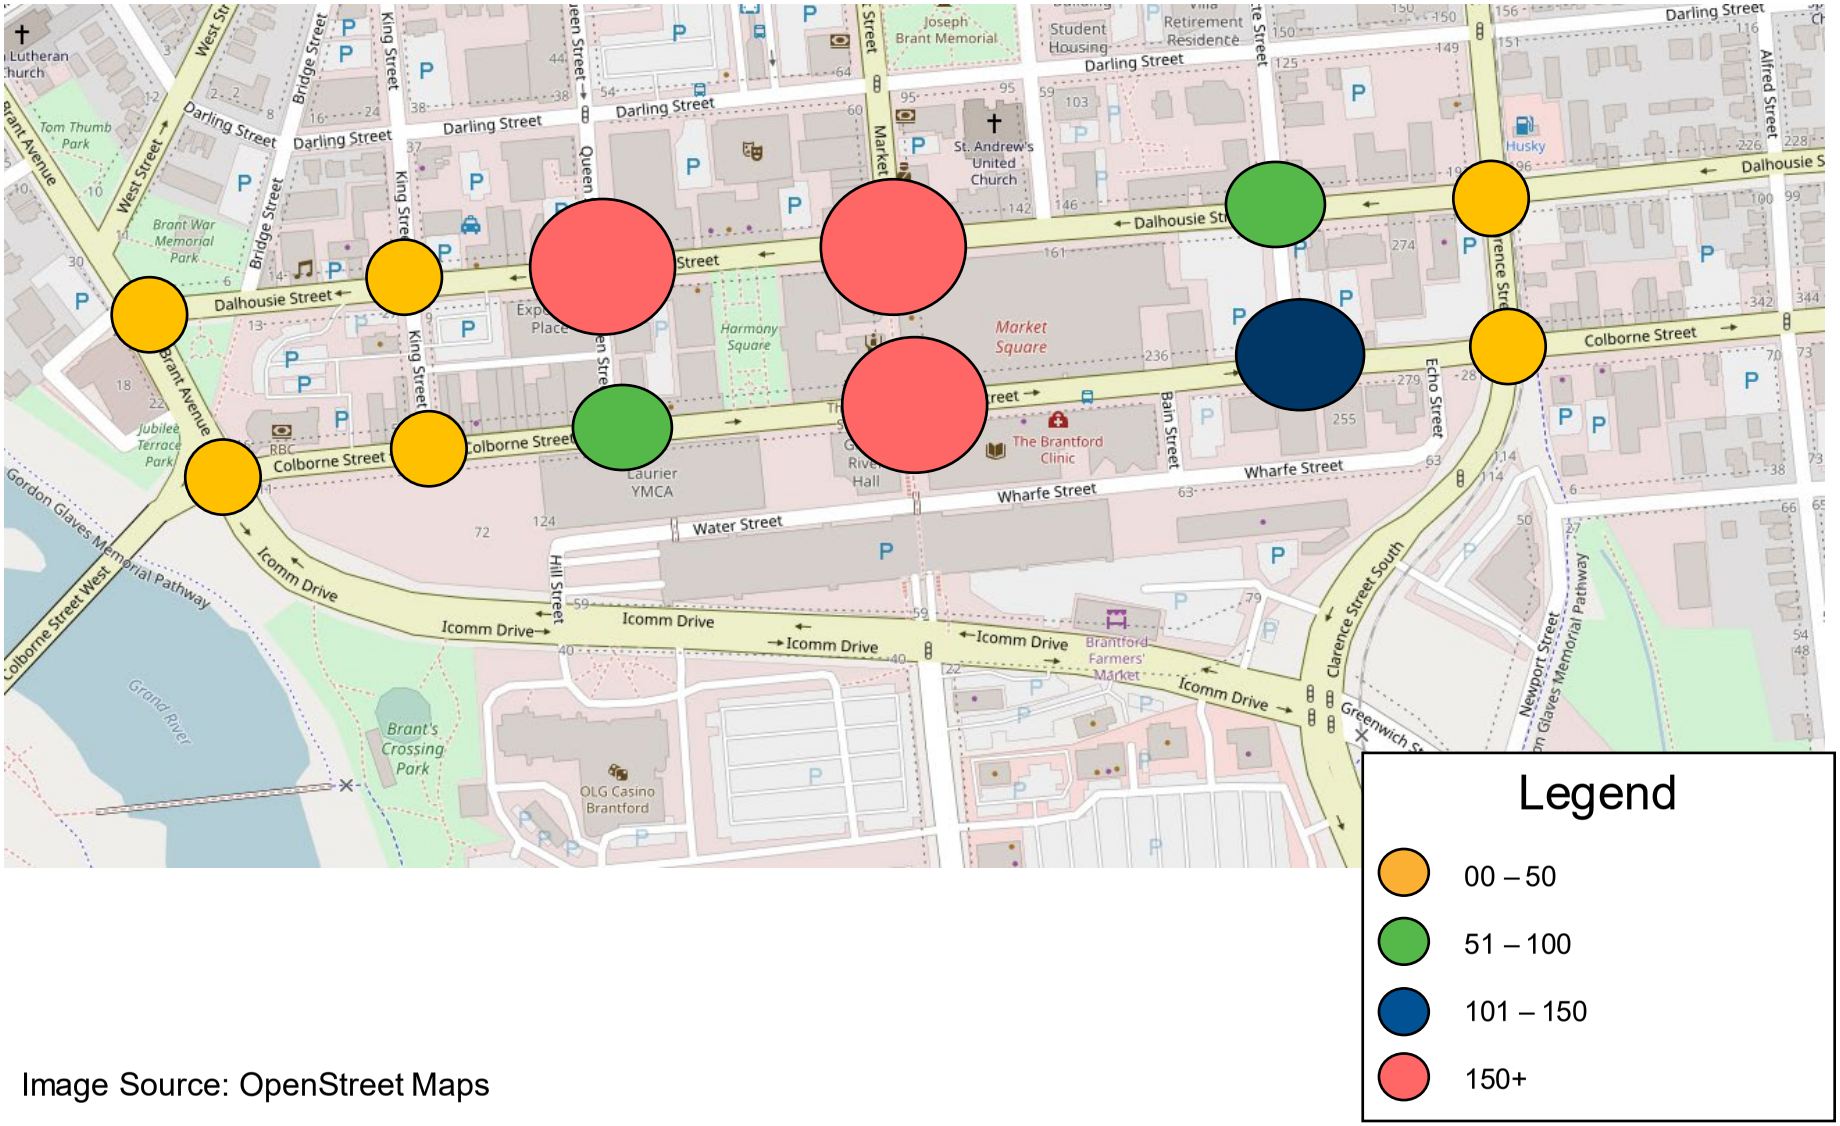

Image Source: OpenStreet Maps

paradigm TRANSPORTATION SOLUTIONS LIMITED

Pedestrian Volumes AM Peak Hour

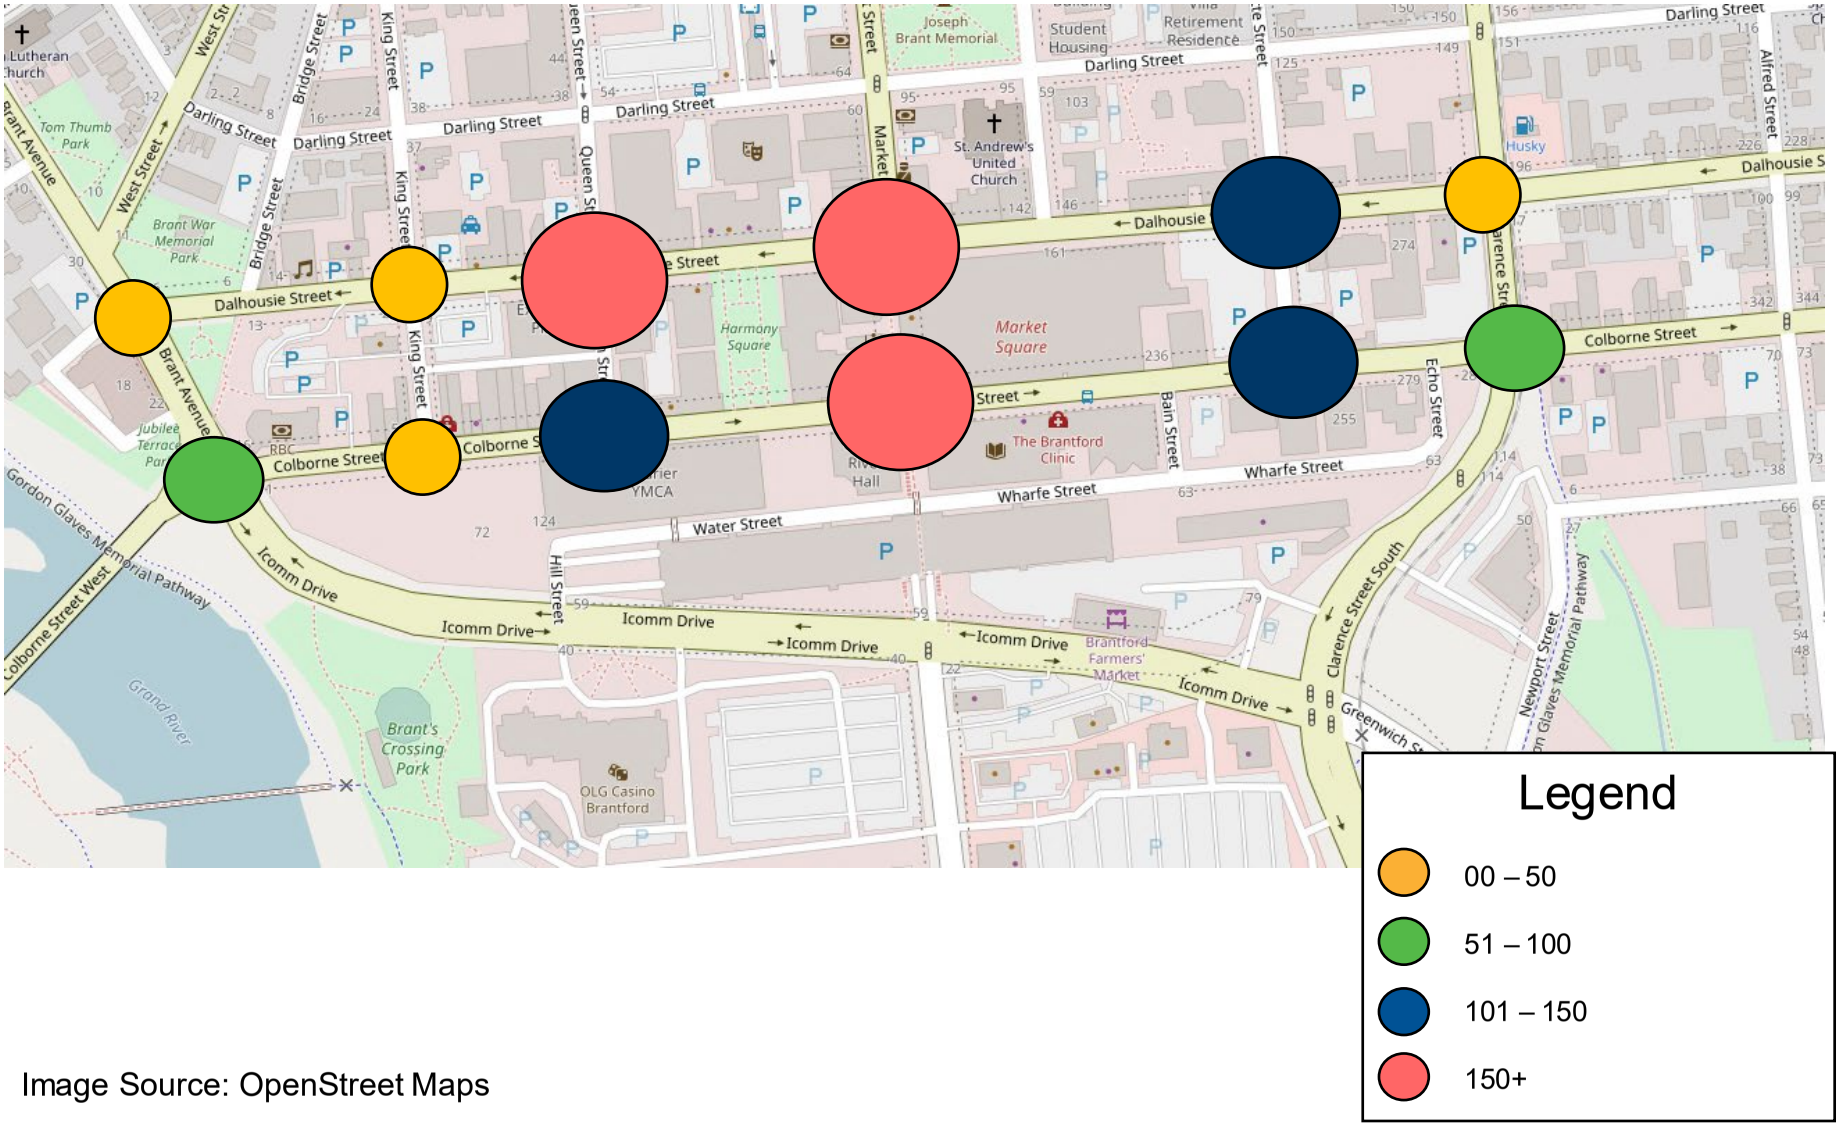

Image Source: OpenStreet Maps

paradigm TRANSPORTATION SOLUTIONS LIMITED

Pedestrian Volumes PM Peak Hour

2.5.2 Cycling

There are no existing cycling facilities along Colborne Street and Dalhousie Street. The Brantford Transportation Master Plan (TMP)[2] identifies these corridors as possible candidates for on-road or in-boulevard facilities. **Figure 2.6** illustrates the proposed cycling connectivity network as outlined in the TMP.

The City's traffic counts and/or Synchro network did not provide cycling data for the intersections within the sub-area. Given limited data, estimates of cycling demand were developed based on the Transportation Tomorrow Survey (TTS). The TTS survey randomly selects households in the Greater Golden Horseshoe (GGH) and is an important data source for transportation planning and is supported by the City of Brantford.

Unlike other data sources, such as regular traffic counts, which measure the change in magnitude of travel demand, the TTS provides information on the characteristics of these changes. As a transportation time series database, the TTS enables analysis on how factors such as flexible work hour programs, relocation of manufacturing employment, and aging population influence how people travel, how often, and the purpose of their trips. TTS data from year 2016[3] (most recent survey) was available for Brantford. This data is comprised of modes of transportation originating in Brantford to destination within and external to Brantford.

Daily cycling trips were reviewed for the entire City to produce a reasonable estimate of the cycling demand. Data from TTS is outlined in **Table 2.3**. The TTS data is provided in **Appendix A**.

[2] City of Brantford, 2020 Transportation Master Plan Update – 2051 Addendum, Dillion, September 2021

[3] Transportation Tomorrow Survey (TTS). 2016. Data Management Group, University of Toronto

TABLE 2.3: 2016 TTS DATA (TRIP MODE)

City of Brantford – Mode Split (All Trips) 2016	
Mode	**%**
Transit (excluding GO rail)	2.3%
Cycle	0.6%
Auto Driver	74.6%
GO Rail only	0.1%
Joint GO rail and local transit	0.0%
Motorcycle	0.1%

Auto Passenger	14.1%
School bus	2.3%
Taxi Passenger	0.3%
Paid Rideshare	0.1%
Walk	5.0%
Total	**100.0%**

Utilizing the TTS data, an estimate of the number of cyclists that could occur along the study area roadways can be developed based on the annual average daily traffic (AADT) volumes. The projected number of daily cyclists along the study area roadways is outlined in **Table 2.4**. Based on the data, Colborne Street and Dalhousie Street could see on average 40 cyclists per day.

TABLE 2.4: 2020 ESTIMATED CYCLING DEMAND

Roadway	Segment		2020 Estimates	
			AADT	Daily Cyclists
Dalhousie Street	Brant Avenue	King Street	7,500	45
	King Street	Queen Street	6,190	37

paradigm TRANSPORTATION SOLUTIONS LIMITED

Proposed Cycling Network

2.6 Traffic Operations

The quality of intersection operations at signalized and unsignalized intersections is evaluated in terms of level of service (LOS) and volume to capacity (v/c) as defined by the Highway Capacity Manual (HCM). LOS is evaluated based on the average control delay per vehicle and includes deceleration delay, queue move-up delay, stopped delay and final acceleration delay.

For signalized intersections, LOS ranges from LOS A (<10 seconds of average delay) to LOS F (>80 seconds of average delay). For unsignalized intersections, the LOS ranges from LOS A (<10 seconds of average delay) to LOS F (>50 seconds of average delay). Capacity is evaluated in terms of the ratio of demand flow to capacity with an at-capacity condition represented by a v/c ratio of 1.00 (i.e. volume demand equals capacity).

The traffic operations in the study area have been evaluated using Synchro 10 with the following parameters:

- Existing lane configurations;
- Signal timing as provided by the City (and included in **Appendix A** for reference);
- Heavy vehicles percentages and pedestrian volumes as extracted from the turning movement counts; and
- Synchro default values for all other inputs.

Synchro implements the methodology of the Highway Capacity Manual (HCM). The intersection analysis considers three different measures of performance:

- The level of service (LOS), based on the average delay for each turning movement, measured in seconds (s);
- The volume-to-capacity (v/c) ratio for each movement; and
- The 95th percentile queue length, in metres (m).

Table 2.5 and Figure 2.7 summarize and note the following

- The Colborne Street corridor generally operates with less than 40 seconds of delay at signalized intersection and less than 5 seconds of delay for unsignalized intersections.

- The Dalhousie Street corridor generally operates with less than 30 seconds of delay for signalized intersections and less than 5 seconds of delay for unsignalized intersections.
- The secondary corridor of Brant Avenue generally operates with less 25 seconds of delay while the Clarence Street corridor operations with just over a minute of delay.
- Overall, the intersections analyzed within the sub-area are operating with acceptable levels of service.

.**Appendix B** contains the detailed Synchro reports.

TABLE 2.5: BASE YEAR TRAFFIC OPERATIONS

3 Road Safety

3.1 Collision Data

The City of Brantford provided collision information for the period of January 1, 2017, to December 31, 2019 (inclusive) at the following locations:

Intersections

- Colborne Street at Brant Avenue;
- Colborne Street at King Street;
- Colborne Street at Queen Street;
- Colborne Street at Charlotte Street;
- Colborne Street at Clarence Street;
- Dalhousie Street at Clarence Street;
- Dalhousie Street at Charlotte Street;
- Dalhousie Street at Market Street;
- Dalhousie Street at Queen Street;
- Dalhousie Street at King Street; and
- Dalhousie Street at Brant Avenue.

Mid-Block Locations

- Colborne Street between Brant Avenue and King Street;
- Colborne Street between King Street and Queen Street;
- Colborne Street between Queen Street and Market Street;
- Colborne Street between Market Street and Charlotte Street;
- Colborne Street between Charlotte Street and Clarence Street;
- Dalhousie Street between Clarence Street and Charlotte Street;
- Dalhousie Street between Charlotte Street and Market Street;
- Dalhousie Street between Market Street and Queen Street;
- Dalhousie Street between Queen Street and King Street; and
- Dalhousie Street between King Street and Brant Avenue.

The data was provided in tabulated form, and included the following information: date and time, weather, impact type, presence of injuries, and road surface condition. Additional information for each driver was provided as follows: direction of travel, vehicle maneuver, vehicle type, and driver action. **Appendix C** contains the raw collision reports.

The collision reports have been reviewed as is. No modifications or adjustments have been made to correct any duplicate entries, or entries for which the collision record appears incorrect (i.e. rear end collision between a northbound and westbound driver).

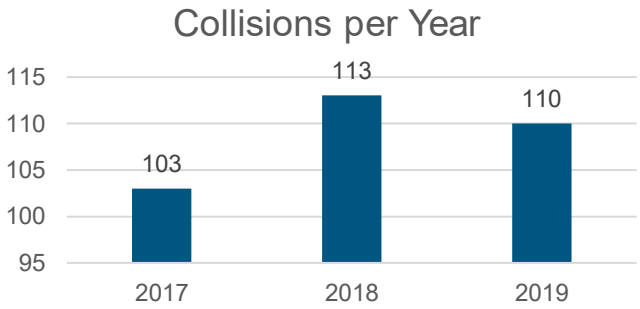
3.1.1 All Collisions

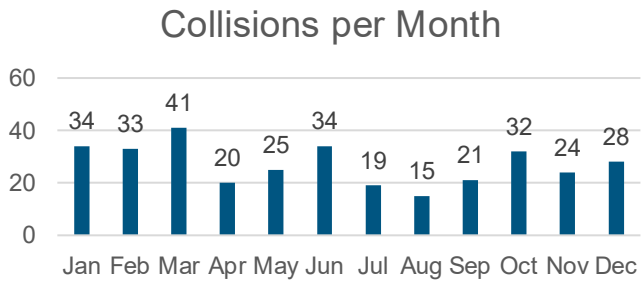
Figure 3.1 shows a summary of all collisions within the study area.

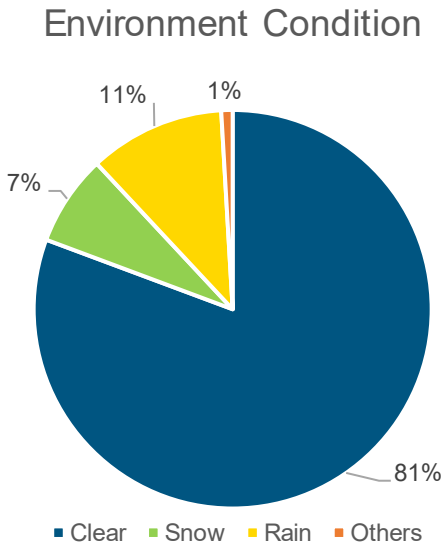
The collision history indicates that environmental conditions were not contributing, as nearly 81% of collisions occurred under a “clear” environment. Accordingly, the data suggest that road surface and environmental conditions do not contribute to a higher frequency of collisions.

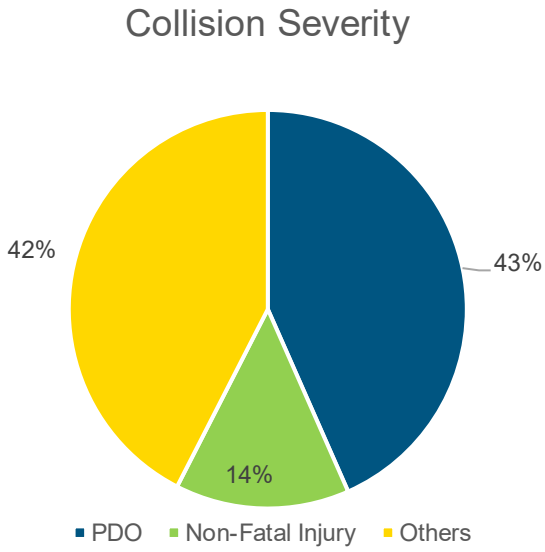
There was one fatality during the periods represented by the data while 43% of all collisions resulted in property damage only and a few (14%) caused non-fatal injuries. The fatal collision occurred at a midblock location in 2019 along Colborne Street between Bain Street and Charlotte Street and is discussed further in **Sub-Section 3.1.3**.

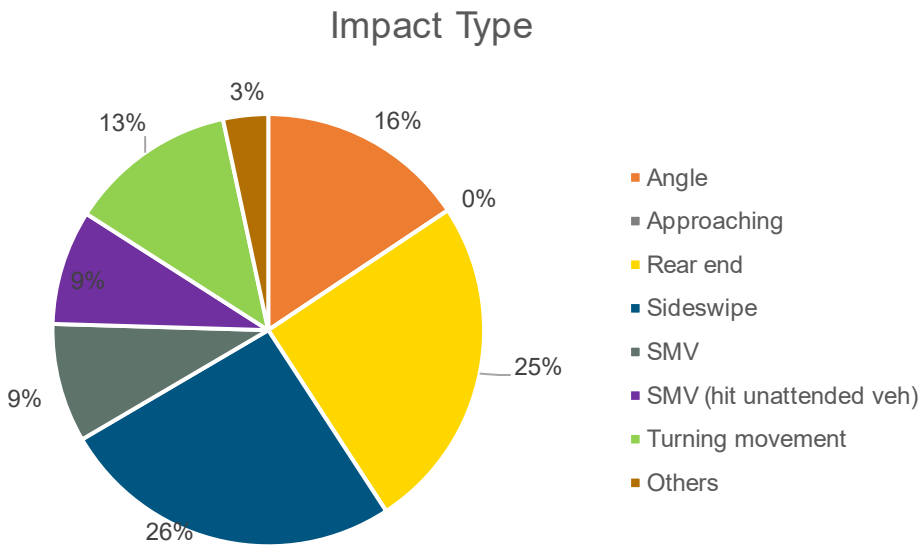
The most common impact types were sideswipe (26%) and rear end (25%). Other type of collisions included turning movements (13%) and angle (16%).











paradigm TRANSPORTATION SOLUTIONS LIMITED

All Collisions Analysis Summary (2017-2019)

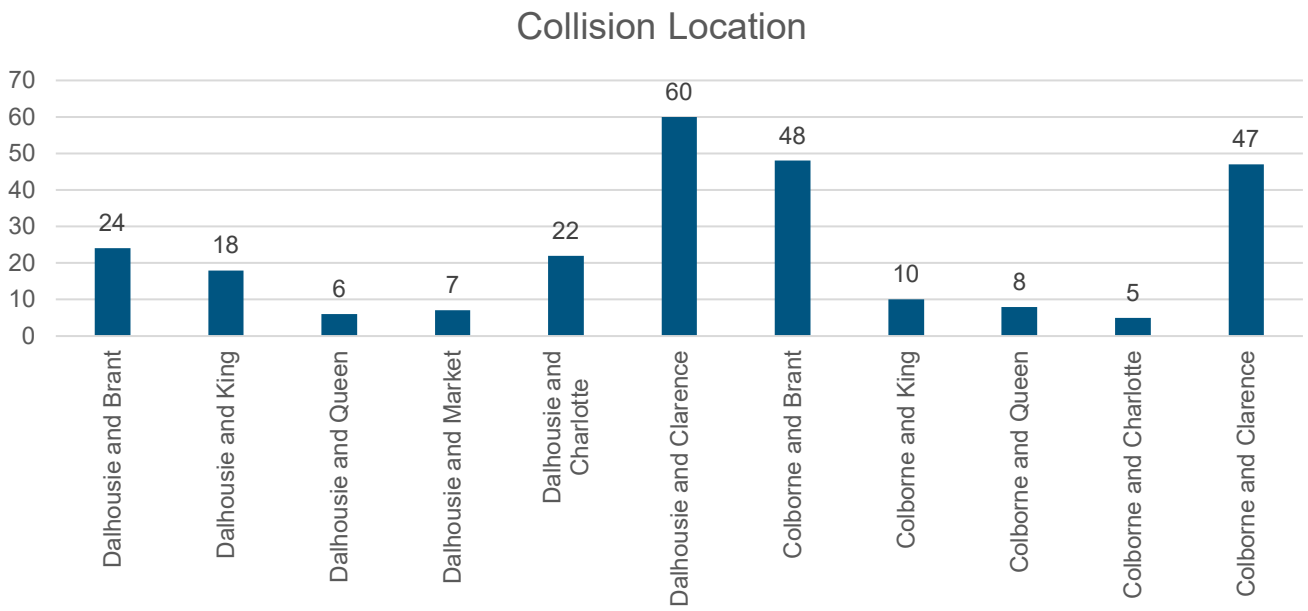
3.1.2 Intersections

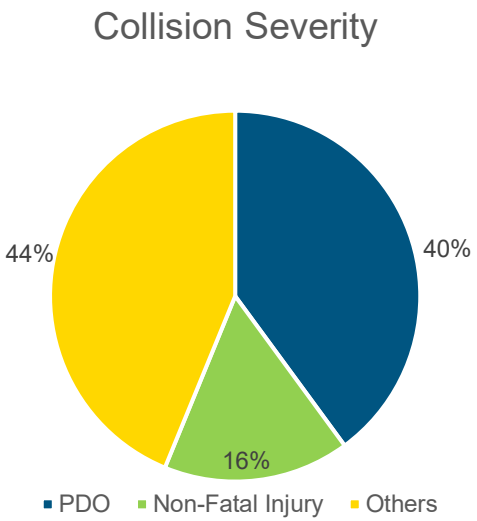
Figure 3.2 shows a summary of all intersection collisions.

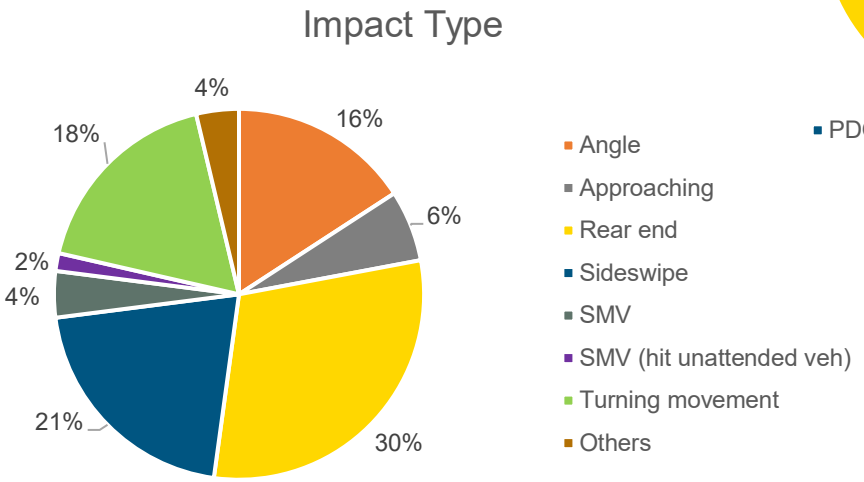
Collision history indicates that the unsignalized intersections within the study area accounted for 18% of the total collisions while the signalized intersection of Dalhousie Street and Clarence Street alone resulted in 24% of all intersection collisions.

There were no fatalities during the periods represented by the data and 40% of all collisions resulted in property damage only and a few (16%) caused non-fatal injuries.

The most common impact types were rear-end (30%) and sideswipe (21%). Other type of collisions included turning movements (18%) and angle (16%).







paradigm TRANSPORTATION SOLUTIONS LIMITED

Intersection Collisions Analysis Summary (2017-2019)

3.1.3 Midblock Segments

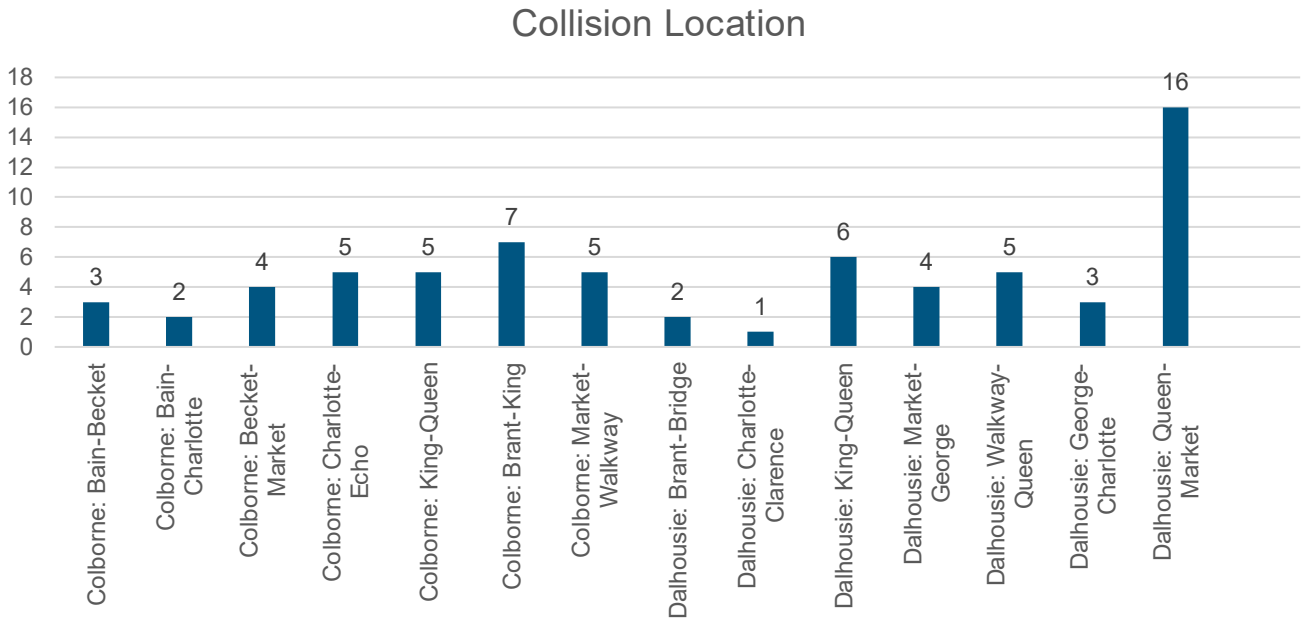
Figure 3.3 shows a summary of all midblock collisions.

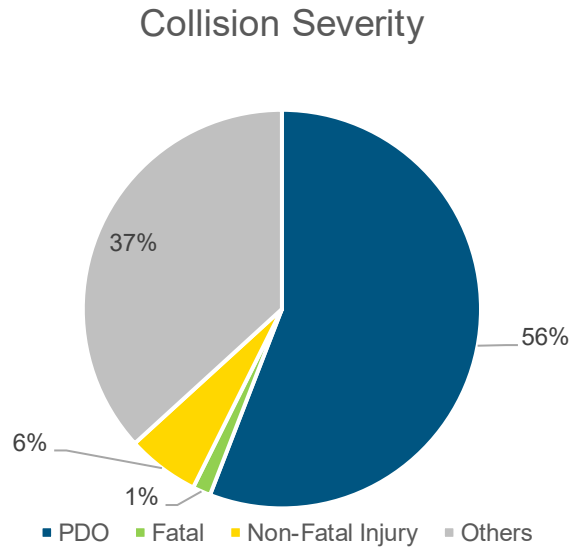
Collision history indicates that the Dalhousie Street midblock segment from Queen Street to Market Street accounted for 24% of all midblock segment collisions followed by the Colborne Street midblock segment from Brant Avenue to King Street (10%).

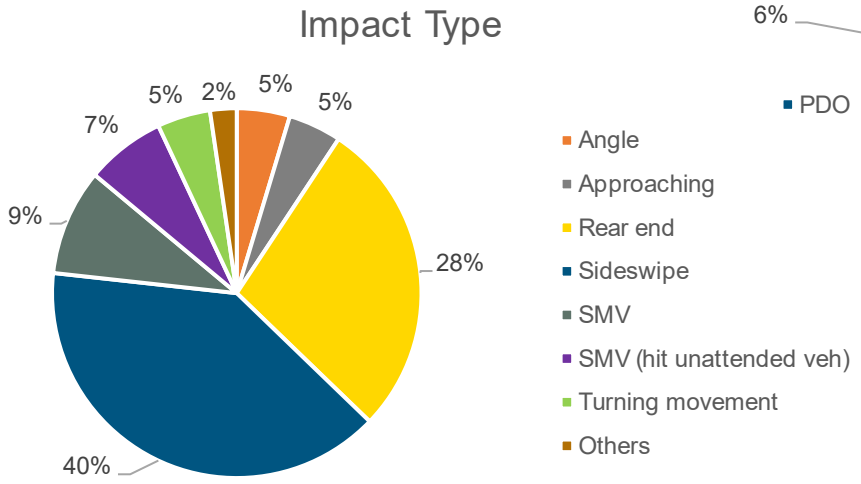
There was one fatal collision that occurred at a midblock location in 2019 along Colborne Street between Bain Street and Charlotte Street that occurred under clear and dry conditions. This collision involved a cyclist that failed to yield the right of way and was sideswiped by a truck travelling in the eastward direction.

The remainder of the collisions can be summarized as 56% of all collisions resulted in property damage only and a few (6%) caused non-fatal injuries.

The most common impact types were sideswipe (40%) and rear-end (28%).







Midblock Collisions Analysis Summary (2017-2019)

3.1.4 Active Transportation Collisions

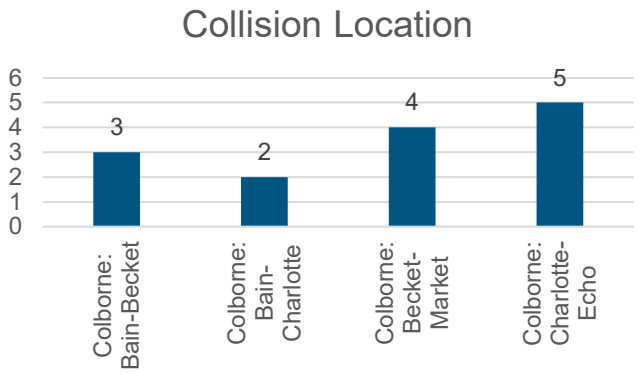
Figure 3.4 shows a summary of all active transportation collisions. From 2017 to 2019 there were a total of 14 collisions (12 pedestrians and 2 cyclist).

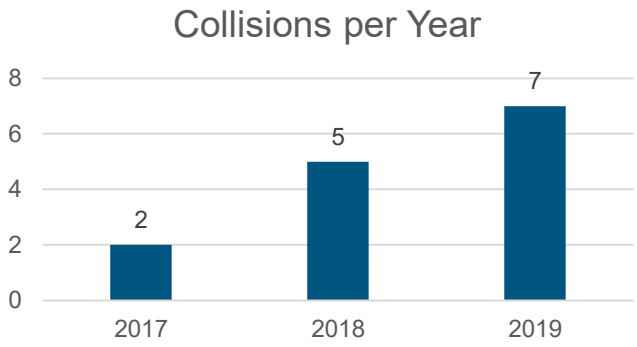
Collision history indicates that the midblock section of Colborne Street between Charlotte Street and Echo Street accounted 35% of all collisions involving a pedestrian or cyclists. The collision history further notes that out of the 14 collisions involving a pedestrian or cyclist, 7 of these collisions occurred in 2019, 5 occurred in 2018 and 2 occurred in 2017.

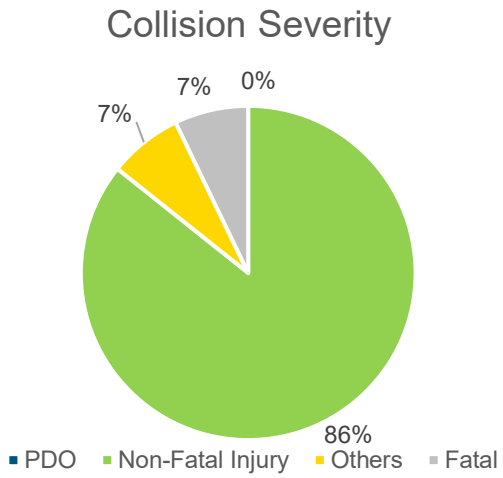
Environmental conditions were not a contributing factor as nearly 86% of all collisions occurred in a clear environment. Accordingly, the data does not imply that road surface and environmental conditions have contributed to the higher frequency of collisions.

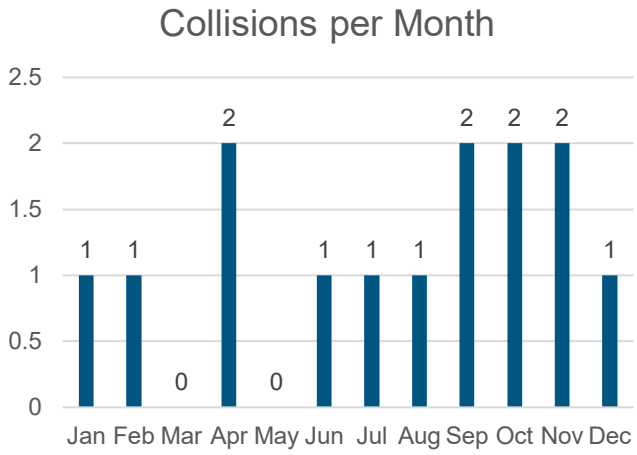
A cycling fatality occurred in 2019 along Colborne Street between Bain and Charlotte Street where the cyclists was sideswiped by a motor vehicle. There were no fatalities involving pedestrians during the periods represented by the data and 86% of all collisions resulted in non-fatal injuries. All collisions involving a pedestrian occurred along sections of Colborne Street without a controlled crossing present.

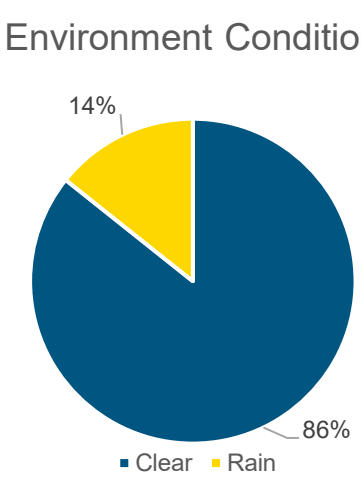
The most common vehicle manoeuvre contributing to active transportation collisions were turning left (57%) and going ahead (29%). Other type of collisions included turning right (14%).

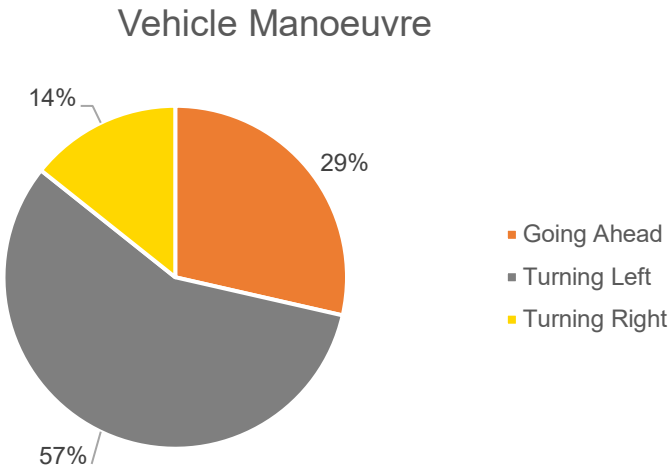












Active Transportation Collisions Analysis Summary (2017-2019)

3.2 Site Assessment

A site visit was conducted in May 2021. The site visit was conducted both by driving and walking through the area, assessing the following roadways and intersections:

Intersections

- Colborne Street at Brant Avenue;
- Colborne Street at King Street;
- Colborne Street at Queen Street;
- Colborne Street at Charlotte Street;
- Colborne Street at Clarence Street;
- Dalhousie Street at Clarence Street;
- Dalhousie Street at Charlotte Street;
- Dalhousie Street at Market Street;
- Dalhousie Street at Queen Street;
- Dalhousie Street at King Street; and
- Dalhousie Street at Brant Avenue.

Roadways

- Colborne Street between Brant Avenue and King Street;
- Colborne Street between King Street and Queen Street;
- Colborne Street between Queen Street and Market Street;
- Colborne Street between Market Street and Charlotte Street;
- Colborne Street between Charlotte Street and Clarence Street;
- Dalhousie Street between Clarence Street and Charlotte Street;
- Dalhousie Street between Charlotte Street and Market Street;
- Dalhousie Street between Market Street and Queen Street;
- Dalhousie Street between Queen Street and King Street; and
- Dalhousie Street between King Street and Brant Avenue.

3.2.1 Colborne Street

Colborne Street intersects with several roadways in the sub study area. Two (2) of the intersections are signalized (Brant Avenue and Clarence Street), while four (4) have side street stop-control, allowing both right and left turns onto Colborne Street, and free flow on Colborne Street (King Street, Bain Street, Charlotte Street and Echo Street). The intersection of Colborne Street and Queen Street is controlled by an all-way stop and a intermediate Pedestrian Signal (IPS) is provided at the Market Street Walkway. Intersections are spaced relatively close together between 45-200 metres with the exception of Echo Street which is located within the functional area of the Colborne Street and Clarence Street intersection.

No cycling facilities are provided, forcing cyclists to share the use of the traffic lanes with motorized vehicles. Some sections of sidewalks provide a clear path of travel for pedestrians, while other sections are obstructed by trees or street furniture or are in need of repairs. All signalized intersections provide pedestrian signals and countdowns, as well as ladder crosswalk pavement markings.

The existing configuration along Colborne Street between Clarence Street and the Market Street IPS provides for a limited number of locations that permit pedestrians to cross Colborne Street as this distance spans approximately 385 metres. One of the most vital strategies to prevent collisions involving pedestrians is to ensure they cross the street at the safest location and to ensure that the locations where pedestrians are likely to cross are as safe as possible.

As all active transportation collisions that have been recorded have occurred within this segment of roadway along Colborne Street, an additional controlled pedestrian crossing is recommended. A typical guideline is to facilitate adequate pedestrian crossings is to maintain at least 200 metres between controlled crossings[4].

[4] Ministry of Transportation, Ontario. Ontario Traffic Manual Book 15: Pedestrian Crossing Treatments, 2016

3.2.2 Echo Street

Echo Street is located approximately 45 metres west of the Colborne Street and Clarence Street signalized intersection and is considered to be within the functional area. As Colborne Street operates with one-way traffic in the eastbound direction, conflicts are reduced. In the event Colborne Street is converted to two-way operation, this would increase the risk of conflicts for northbound vehicles with through traffic on Colborne Street. The spacing of the intersection is also problematic under the two-way scenario as northbound left turning traffic from Echo Street onto Colborne Street would likely have visibility concerns exiting onto Colborne Street as a result of queueing from the signalized intersection with Clarence Street.

3.2.3 Dalhousie Street

Dalhousie Street intersects with several roadways in the sub study area. Five (5) of the intersections are signalized (Brant Avenue, King Street, Queen Street, Market Street, and Clarence Street), while three (3) have side street stop-control, allowing both right and left turns onto Dalhousie Street, and free flow on Dalhousie Street (Bridge Street, George Street and Charlotte Street), Bain Street, Charlotte Street and Echo Street). The south leg of Dalhousie Street and Market Street is restricted to active transportation modes only. Intersections are spaced closely together, with distances between intersections varying between 65 - 200 metres.

No cycling facilities are provided, forcing cyclists to share the use of the traffic lanes with motorized vehicles. Some sections of sidewalks provide a clear path of travel for pedestrians, while other sections are obstructed by trees or street furniture or are in need of repairs. All signalized intersections provide pedestrian signals and countdowns, as well as ladder crosswalk pavement markings.

3.2.4 Bridge Street

The Bridge Street intersection is very close to the intersection with Dalhousie Street and Brant Avenue creating a number of conflicts for southbound right turning vehicles as a result of the westbound queue created from the signalized intersection upstream. This was noted to be primarily problematic for vehicles from Bridge Street that wanted to travel southbound along Brant Avenue. As Dalhousie Street operates with one-way traffic in the westbound direction, a potential mitigation solution could entail limiting Bridge Street to one-way operation in the northbound direction.

In the event Dalhousie Street is converted to two-way operation, the spacing of the intersection is problematic as eastbound left turning traffic from Dalhousie Street onto Bridge Street would likely encounter queuing from the signalized intersection of Dalhousie Street with Brant Avenue that could impact the operations.

3.2.5 Brant Avenue

A review of the lane configuration on Brant Avenue between Dalhousie Street and Colborne Street indicates the curb lane becomes a right-turn lane. The centre lane remains a through lane, and a shared left/through lane is introduced approaching Colborne Street. Overhead lane configuration signs are installed 40 metres north of Dalhousie Street, directing motorists to the correct lane depending on their desired route (e.g., south via Icomm Drive or west via Colborne Street). Overhead signs are also provided on Dalhousie Street, with dedicated signs for the two left-turn lanes provided on the westbound approach.

Driver confusion or inattentiveness is likely a key contributor to increased sideswipe and rear end collisions at this location. This is exacerbated by the intersection spacing between Brant Avenue/Dalhousie Street and Brant Avenue/Icomm Drive/Colborne Street.

Based on field observations, the intersection does not include tracking pavement markings for the dual eastbound left turn movement. Ontario Traffic Manual (OTM) *Book 12*[5] notes that "*a dual LTL [left turn lane] shall require pavement marked 'tracking' lines for guidance of turning vehicles*" (pg. 156). Consideration could also be given to modifying the existing shared eastbound left-turn/through lane to an exclusive left-turn lane, or exclusive through lane. This would seek to eliminate slip around maneuvers from through volumes who may be stuck behind a left-turning vehicle when waiting for a pedestrian to cross the north approach of the intersection.

The intersection also includes an uncontrolled pedestrian crossing of the southbound channelized right-turn movement. The collision history does not identify any collisions relating to the uncontrolled crossing; however, this can present a conflict between vehicles and pedestrians. The conflict is exacerbated by the high volume of right-turning traffic (approximately 1,200 vehicles in the PM peak hour, or one every three seconds) at this intersection. This volume of traffic

[5] Ministry of Transportation, Ontario. Ontario Traffic Manual Book 12: Traffic Signals. March 2012.

provides very limited crossing opportunities for pedestrians. Removal of the channelization or conversion to a “smart channel” design may reduce conflicts between vehicles and pedestrians.

However, given the large volumes of southbound right turning vehicles, removal of the channelization would likely have an impact on operations along Brant Avenue. Instead, the installation of a Pedestrian Crossover (PXO) would provide for a controlled crossing opportunity for pedestrians while still maintaining capacity to serve the high volume of southbound right turns.

3.2.6 Queen Street

Queen Street is noted be narrow in width with a sidewalk provided on both sides of the road and no cycling facilities. Provisions to upgrade active transportation facilities does not appear to be feasible. Additionally, there are a number of driveway providing access to parking facilities off of Queen Street adjacent to a number of buildings with what appears as zero setback lot lines that have poor visibility for outbound vehicles at these driveways.

3.3 Mitigation

To improve the potential safety hazards within the sub study-area, the implementation of a blanket 40 kilometres posted speed limit along Colborne Street and Dalhousie Street is preferred. Furthermore, improved sidewalks (i.e., wider with limited to no obstructions) and cycling facilities will need to be incorporated. Ultimately, the preferred design and streetscape design should support these recommendations.

Other improvements that may need to be considered in the final design could include bike signals, pedestrian-only phases (reserved for intersections with high pedestrian volumes) and pedestrian-leading green time to provide pedestrians with an advanced opportunity to cross before vehicles are allowed to proceed right. Additionally, the measures identified above are further recommended for consideration:

- The intersection of Dalhousie Street and Bridge Street be modified to only one-way traffic in the northbound direction to reduce the number of potential conflicts with westbound through traffic.
- The intersection of Colborne Street and Echo Street be modified to right in/out operations under the two-way traffic scenario to reduce the number of potential conflicts and operational issues at the downstream signalized intersection at Clarence Street.

- To mitigate the number of active transportation collisions along Colborne Street between the Market Street IPS and Clarence Street, an additional controlled crossing be considered to improve the crossing opportunities for pedestrians. In terms of improvements for cyclists, a protected bike lane is recommended for Colborne Street and Dalhousie Street to protect cyclists from passing traffic.

3.4 Review of Alternatives

Table 3.1 reviews the proposed alternatives from a road safety perspective. The criteria are compared to the Do-Nothing scenario and indicate:

- **Alternative 1:** Least favorite as sidewalks have obstructions, no provisions for bikes.
- **Alternative 2:** This alternative is in-line with the overall vision as it provides dedicated cycling facility provides high level of cyclist safety as bike lanes are fully protected. Maintains parking on one side of the street that is separated and provides narrow the travel lanes to reduce speeds. Pedestrian space however is not any wider than the existing.
- **Alternative 3:** This alternative is in-line with the overall vision as it provides dedicated cycling facility provides high level of cyclist safety as bike lanes are fully protected. Maintains parking on one side of the street that is separated and provides narrow the travel lanes to reduce speeds. Pedestrian space however is not any wider than the existing.
- **Alternative 4:** This alternative is in-line with the overall vision as it provides dedicated cycling facility provides high level of cyclist safety as bike lanes are fully protected. Maintains parking on one side of the street that is separated and provides narrow the travel lanes to reduce speeds. Pedestrian space however is not any wider than the existing.
- **Alternative 5:** This alternative is in-line with the overall vision as it provides dedicated cycling facility provides high level of cyclist safety as bike lanes are fully protected. Maintains parking on one side of the street that is separated and provides narrow the travel lanes to reduce speeds. Pedestrian space is also expanded.

TABLE 3.1: ROAD SAFETY REVIEW OF ALTERNATIVES

Alternative	Impacts
1 (Do-Nothing)	No bike facilities provided and no increased pedestrian space.
	Higher risks of conflicts at intersections between bikes and right-turning vehicles since no separate bike facilities.
2 (Two-Way Bi-Directional Cycle) 3 (Two-Way Separated Cycle) 4 (One-Way Bi-Directional Cycle)	No Increased pedestrian space.
	Separated pedestrian and bike facilities. Ensure enough space is kept for pedestrians with the furnshied zone (i.e. do not limit sidewalk and obstruct pedestrian clear path)
	Separated bi-drectional cycle tracks, lower conflicts for bike/vehicles
	Careful with treatment of bikes at intersections – mixed with vehicles or bike crossings (bike signals allowed in Ontario, could be considered)
	Overall best option for bikes since they have designated facilities
5 (One Way Separated Single Cycle)	Increased pedestrian space.
	Separated pedestrian and bike facilities. Ensure enough space is kept for pedestrians with the furnshied zone (i.e. do not limit sidewalk and obstruct pedestrian clear path)
	Separated bi-drectional cycle tracks, lower conflicts for bike/vehicles
	Careful with treatment of bikes at intersections – mixed with vehicles or bike crossings (bike signals allowed in Ontario, could be considered)
	Overall best option for pedestrians as increased space is achieved, parking and bikes are seperated.

4 Future Demand

The following section documents the future conditions in the sub-area including population and employment forecasts and the traffic forecasting methodology, and future traffic volumes for three analysis scenarios, and a level of service analysis resulting in a preferred scenario. At the outset of this study, City staff determined the study would need to include projections for years 2025, 2030 and 2051.

4.1 Future Population and Employment Growth

Because of the direct relationship between land use and transportation demand, the City of Brantford's Transportation Master Plan Update (TMPU) growth projections are documented as a critical input in assessing future transportation conditions. While many other factors can influence transportation demand, the City's projections (or any potential variations) provide the strongest indicator of areas which may have changing transportation needs.

The City of Brantford is expected to see rapid growth between 2016 and 2051. **Table 4.1** shows that the City of Branford population is expected to increase by 62% (approximately 63,300 additional people) and employment by 78%, adding 35,100 jobs by the year 2051.

TABLE 4.1: POPULATION AND EMPLOYMENT ASSUMPTIONS

Measure	2016	2031	2051
Population	101,700	139,000	165,000
Employment	44,900	67,000	80,000

Forecasts based on 2020 TMPU Addendum

Based on current growth and growth anticipated in the expanded urban boundary, the following trends to the 2051 horizon year are noted:

- High employment growth in the Oak Park Road & Hardy Road (Northwest Industrial Park) and Henry Street/Wayne Gretzky (Braneida Industrial Park) areas;
- High employment growth in the expansion lands east of Garden Avenue at Highway 403 and north of Powerline Road just east of Paris Road;
- High population growth in the southern zones surrounding Shellard Lane, Mt Pleasant Road and Erie Avenue;

- High population growth in the northern expansion zones (north of Powerline Road) from Balmoral Drive in the west to Coulbeck Road in the east;
- High population and employment growth along the King George Road corridor; and
- High population and employment growth in the downtown core.

Intensification within downtown Brantford will increase the densities and transform the area into an urban area that will focus on contributing to a modal shift away from the single occupancy vehicle as the distance to many amenities will decrease, making them more bikeable and walkable. In contrast, transit service will increase as higher densities support higher service frequency.

4.2 Balanced Needs Approach

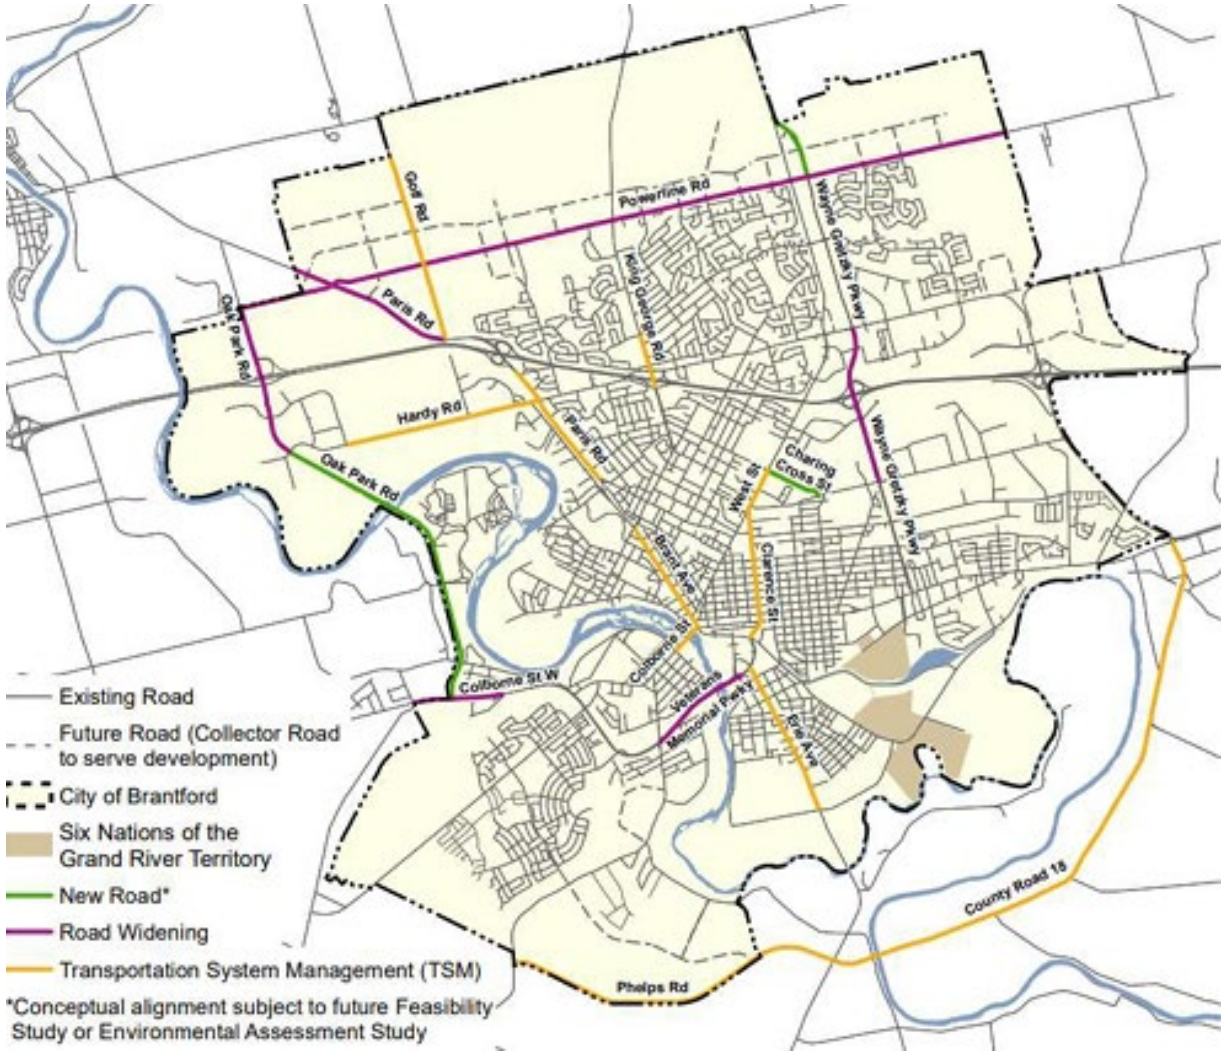
Brantford's population and employment growth is forecast to continue until 2051 at a rate of approximately 2% per year. These increases will call for a focus on the development of an efficient and effective transit system if mobility within the community and between Brantford and adjacent municipalities is to support the City's economy and residents' quality of life.

Brantford's forecasted growth will significantly alter the local travel demands within the city and by 2051 Brantford is forecast to generate more than 85,900 AM peak period person trips on an average weekday. That's an increase of nearly 72% over 2016 person trips. With population and employment growth, there will be an increase in demand on the road network where some corridors will likely experience or approach capacity constraints.

The TMPU's preferred solution to address the forecast growth of the City to 2051 is a combined solution that involves:

- Transit service improvement/enhancements to promote increased transit use;
- The provision of active mode infrastructure to promote increased cycling and walking; and
- Network infrastructure improvements to address the capacity constraints in the network.

With that said, capacity/operational issues under the 2051 horizon are expected to remain along the Lorne Bridge as well as along Clarence Street. **Figure 4.1** illustrates the 2051 recommended roadway plan.



2051 Recommended Roadway Network

Figure 4.1

Table 4.2 indicates that with the proposed TMPU-identified combined solution approach, an increased transit, walking and cycling mode share is targeted for 2051.

TABLE 4.2: MODAL SPLIT ASSUMPTIONS

Mode	2016	2051	Difference
Auto Driver	70.8%	67.5%	-3.3%
Auto Passenger	14.6%	12.5%	-2.1%
Transit	2.8%	5.8%	3.0%
Cycle/Walk	7.8%	9.9%	2.1%
Other	4.0%	4.3%	0.3%

The population and employment forecasts along with the target mode share were used in the EMME model to develop transportation scenarios.

4.3 Traffic Forecasting Methodology

To forecast 2025, 2030 and 2051 demand based on the population and employment scenarios outlined, the City's model forecasts from the 2016 model and the 2051 recommended plan models are utilized to determine compound annual growth rates for each segment within the sub-area. **Appendix D** illustrates the model forecasts.

As it is recognized that data from regional models is not as necessarily accurate for individual movements; but rather, the model projects overall travel characteristics along transportation corridors, separate rates have been calculated for each segment within the sub-area and have been applied to the adjusted base year traffic volumes.

Table 4.3 summarizes the applied growth rates for the one-way scenario. The model generated traffic growth rates reflect planned population and employment growth previously identified and includes transit service improvement, active mode infrastructure, and network infrastructure improvements. Each of these factors impacts upon travel patterns and traffic volumes within the sub-area and in some instances, results in reduced vehicle demand.

TABLE 4.3: ONE-WAY COMPOUND ANNUAL GROWTH RATES

2020 - 2051 Compound Annual Growth Rates				
Colborne Street	AM Peak Hour		PM Peak Hour	
	EB	WB	EB	WB
Brant to King Street	1.6%	-	0.4%	-
King Street to Queen Street	1.0%	-	1.0%	-
Queen Street to Charlotte Street	1.3%	-	0.6%	-
Charlotte Street to Clarence Street	1.5%	-	0.5%	-
Clarence Street to Dalhousie Junction	2.7%	-	0.9%	-
Dalhousie Street	AM Peak Hour		PM Peak Hour	
	EB	WB	EB	WB
Brant to King Street	-	0.8%	-	0.7%
King Street to Queen Street	-	0.7%	-	0.2%
Queen Street to Market Street	-	0.6%	-	0.2%
Market Street to Charlotte Street	-	0.4%	-	0.2%
Charlotte Street to Clarence Street	-	0.7%	-	0.2%
Clarence Street to Colborne Street Junction	-	1.0%	-	1.0%

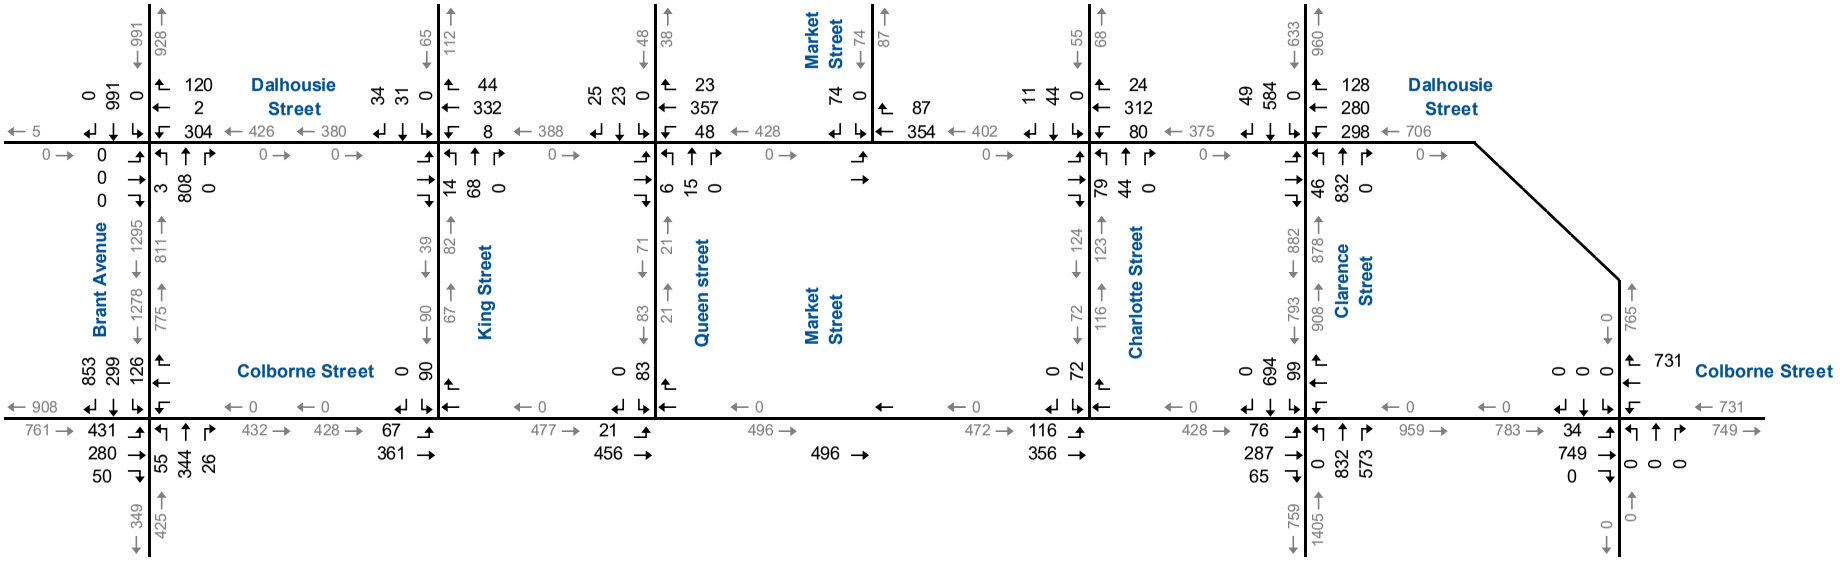
4.4 One-Way Traffic Volumes

Based on the forecast methodology outlined in the previous section, the future traffic volumes within the sub-area were calculated at the intersection turning movement level of detail for the entire corridor for the weekday peak hour traffic scenarios. Traffic volume forecasts at each intersection are illustrated in **Figures 4.2 – 4.4**. Note that intersection traffic volumes are only summarized at major intersections within the sub-area.

It is noted that changing factors such as fuel prices, electric cars, car sharing, socio-demographic changes, lower auto-ownership levels, and intensification resulting in increased density and better proximity/accessibility to destinations all impact travel patterns, modes and rates of travel to some degree. However, it is difficult to quantify these changes without a model calibrated to consider such factors. As such, the results presented within this report can be considered conservative because many of the above-stated factors generally result in reduced peak period automobile travel.

Forecast peak hour traffic volumes by major road segments compared to existing traffic volumes to the 2051 traffic volumes for the one-way scenario are summarized in **Figure 4.5.**

The projections indicate that volumes are expected to be within the available capacity under the one-way scenario. It should be noted, however, the assumed capacity is considered “ideal”. In reality, the ideal capacity is rarely achieved in the field as a result of numerous non-recurring factors, including collisions/lane closures, friction in the shoulder lane from bus activity, turning movements to/from mid-block driveways, the presence of parked cars within a travel lane, etc.



2025 AM Peak Hour Traffic Volumes

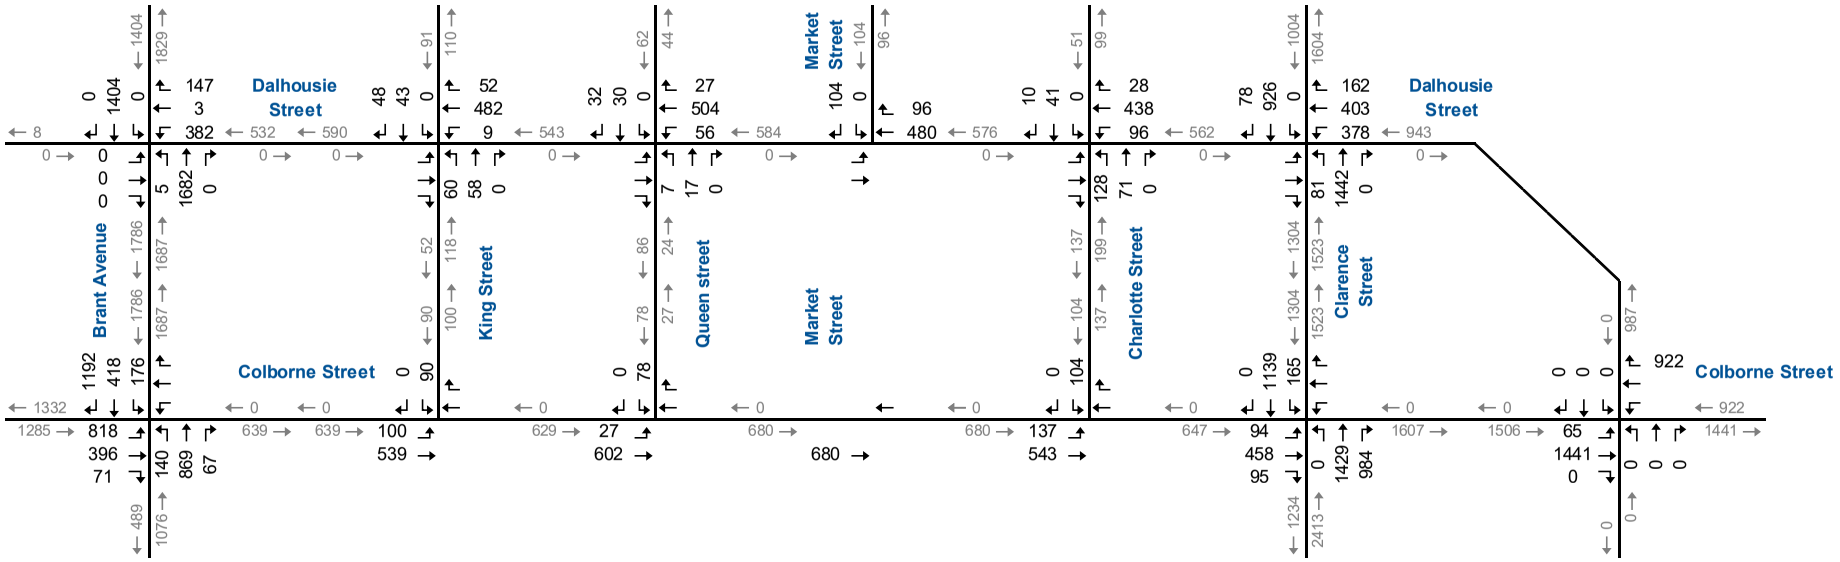
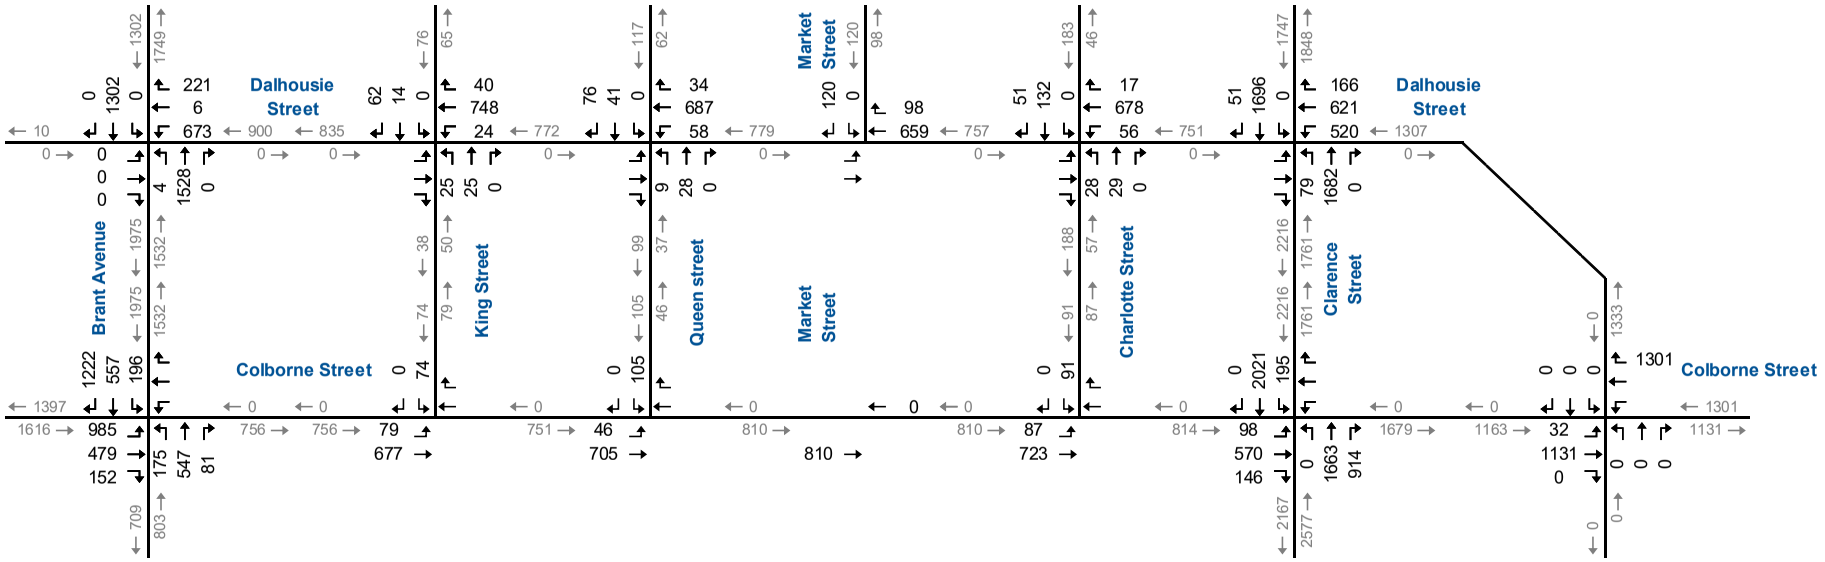
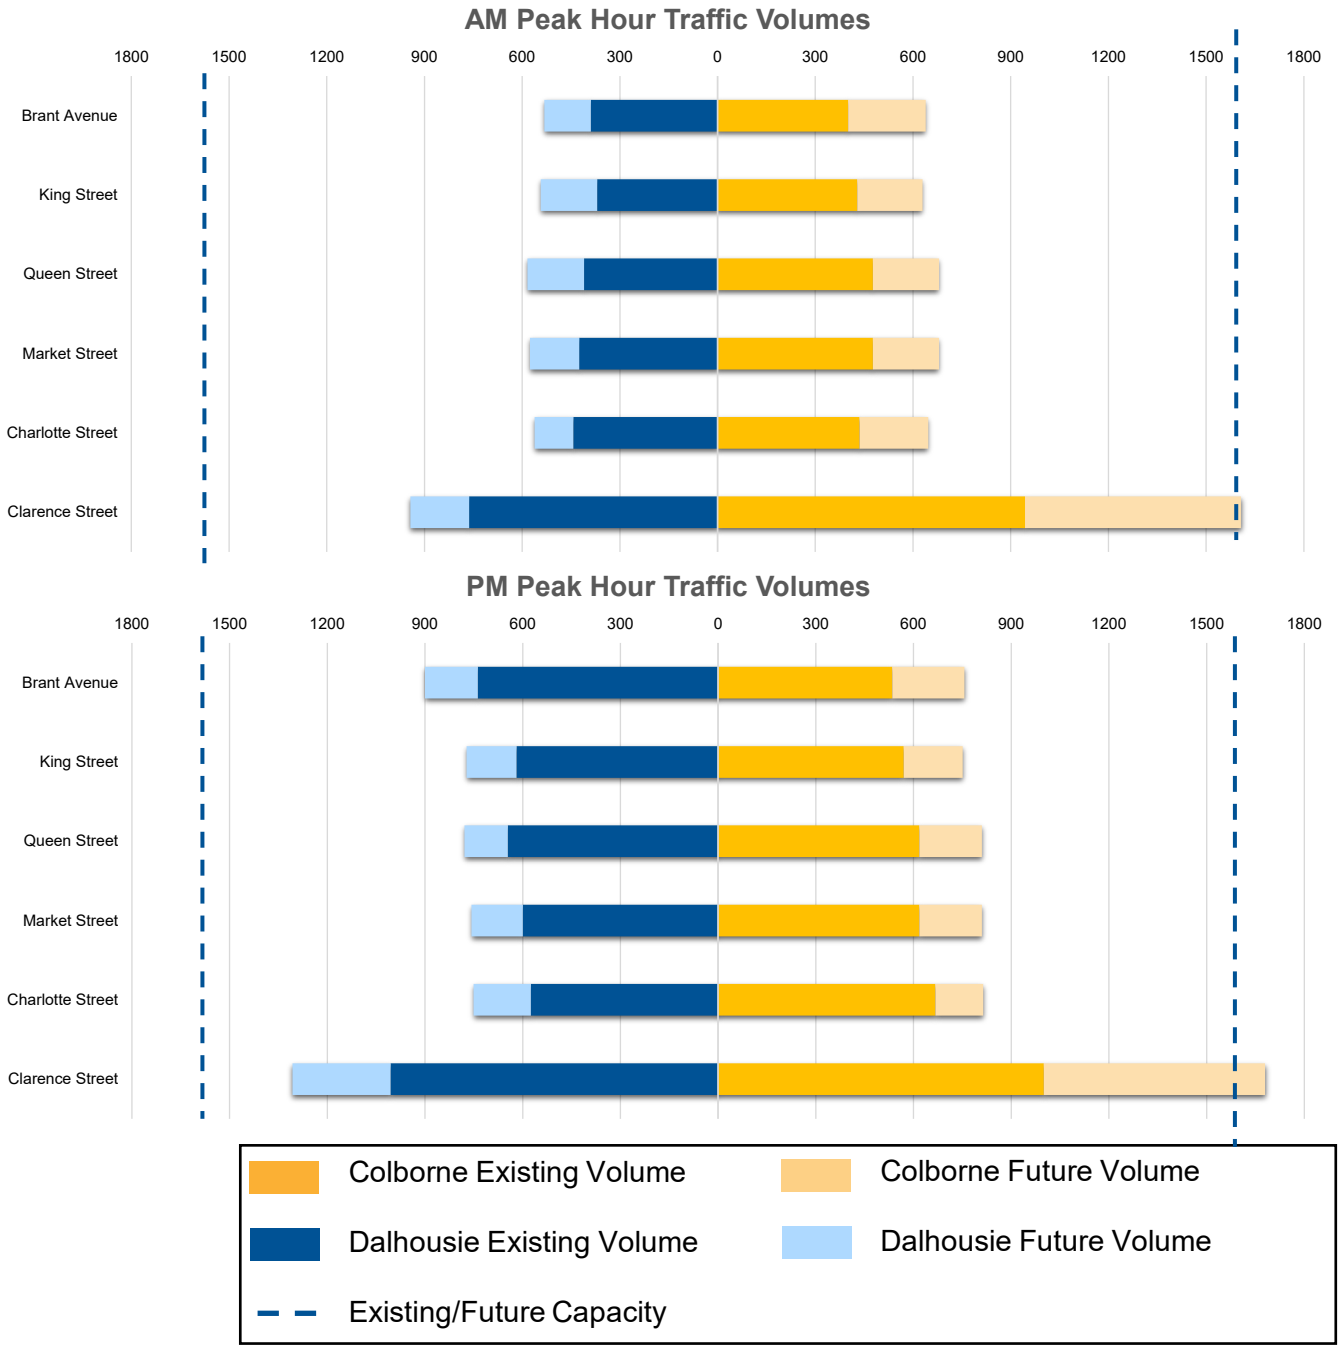
Figure 4.3B



2051 AM Peak Hour Traffic Volumes



2051 PM Peak Hour Traffic Volumes



2051 Capacity Comparison (One-Way)

4.5 Two-Way Traffic Volumes

One of the determinants of how future traffic patterns will change with growth and different street configuration options is trip distribution (origin-destination) data. To develop the reassignment under a two-way scenario, a refinement to the City's travel forecasting model analysis zones and network was carried out to create a sub-area model of the downtown network to assist with the distribution.

The one-way traffic in the downtown area was than reassigned to a two-way system based on the trip origin and destination information as projected in the analysis zones. Travel routes were then developed in and out of the downtown area based on the most direct route to these zones which indicates 60% of through traffic would favour Colborne Street whereas 40% of through would favour Dalhousie Street.

The reassignment was than compared with the roadside interview origin-destination data collected as part of the previously completed EA "Conversion of Colborne Street and Dalhousie Street to Two-way Traffic Operation" completed in 2010 which indicates similar trends.

Based on the forecast methodology, the future traffic volumes within the sub-area under the two-way scenario were calculated. Traffic volume forecasts at each intersection are illustrated in **Figures 4.6.**

Forecast peak hour traffic volumes by major road segments for the 2051 traffic volumes for the two-way scenario are summarized in **Figure 4.7.**

Traffic volumes are anticipated to increase moderately along Dalhousie Street and significantly along Colborne Street which is projected to exceed the capacity of a single through lane approach at the eastern limit of the study area. It should be noted, however, the assumed capacity is considered "ideal". In reality, the ideal capacity is rarely achieved in the field as a result of numerous non-recurring factors, including collisions/lane closures, friction in the shoulder lane from bus activity, turning movements to/from mid-block driveways, the presence of parked cars within a travel lane, etc.

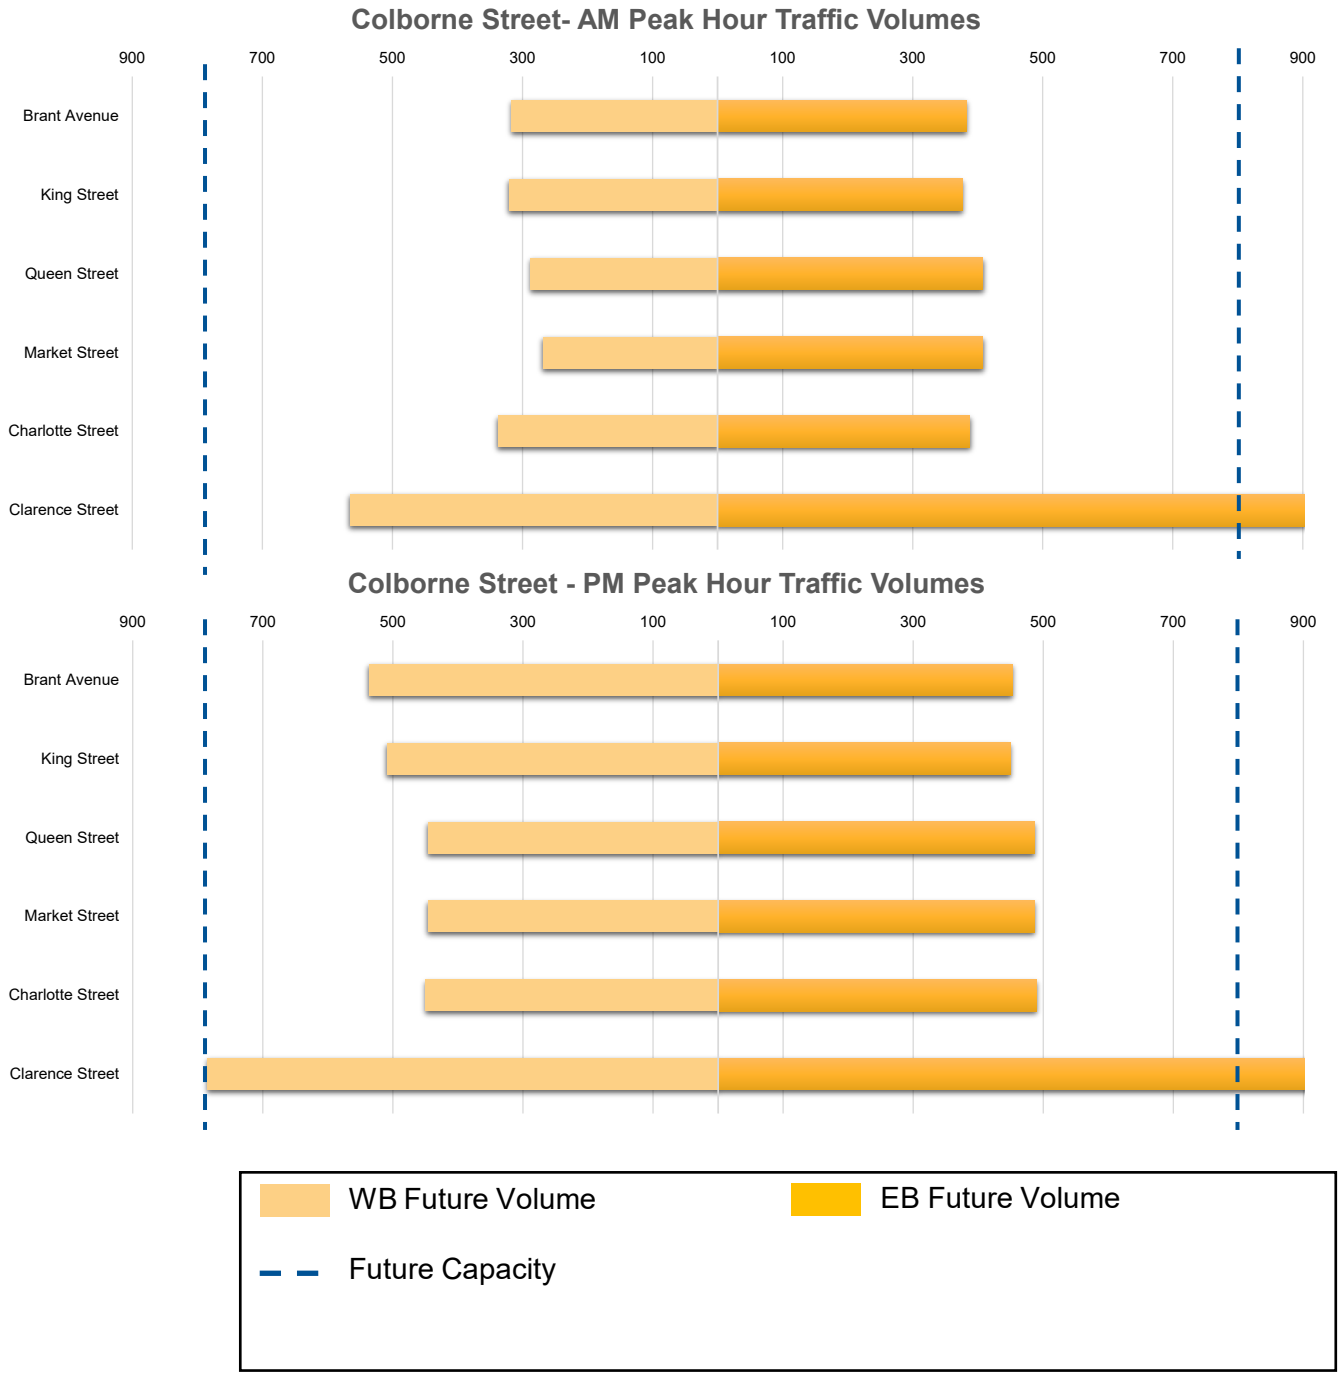
2051 Dalhousie Street Capacity Comparison (Two-Way)



2051 Colborne Street Capacity Comparison (Two-Way)

5 Future Operations

Future intersection Level of Service (LOS) was assessed based on the methodology described in **Section 2.6**. The following analyses summarize lane configuration assumptions, forecast AM and PM LOS, critical movements, v/c ratio, and total delay for critical movements for the 2051 operations under one-way and two-way scenarios, respectively.

The future traffic conditions assessments are based on intersection capacity as link capacity is dictated by the downstream intersection. Critical movement delays represent a worst-case scenario and are subject to the limitations of the Synchro model assumptions and traffic and signal timing inputs. Much of the City of Brantford's traffic signal system can adjust timings to meet changing traffic conditions.

5.1 One-Way Traffic Volumes (2051)

Table 5.1 summarizes the lane configuration assumptions, the AM and PM LOS, the critical movements v/c ratio, and the total delay for the 2051 one-way operational analysis. **Figure 5.1** graphically displays the results and note:

- Overall, the intersections analyzed within the sub-area are operating with satisfactorily levels of service. In both the AM and PM peak hours, intersection LOS A-C is anticipated.

  Localized congestion is projected to occur along the Clarence Street Corridor during the PM Peak hour and is likely a result of the left turn movements along Clarence Street being shared with the through movement. As the majority of trips on Clarence Street are travelling from north-central Brantford (i.e., north of Highway 403) to the south side of the river via West Street. A widening of Clarence Street to provide for separate left turn lanes would improve operations. Alternatively, the Veterans Memorial Parkway partial extension (to Murray Street) provides an opportunity for an alternative route out of downtown via Murray Street. A partial extension of the Veterans Memorial Parkway could be considered beyond 2051 to address potential long-term issues and should be protected for as an alternative to Clarence Street.

Appendix D contain the supporting detailed Synchro.

TABLE 5.1: 2051 (ONE-WAY) TRAFFIC OPERATIONS

Intersection	Lane Configuration	LOS AM	LOS PM	Critical Movements LOS - V/C - Delay	Intersection	Lane Configuration	LOS AM	LOS PM	Critical Movements LOS - V/C - Delay

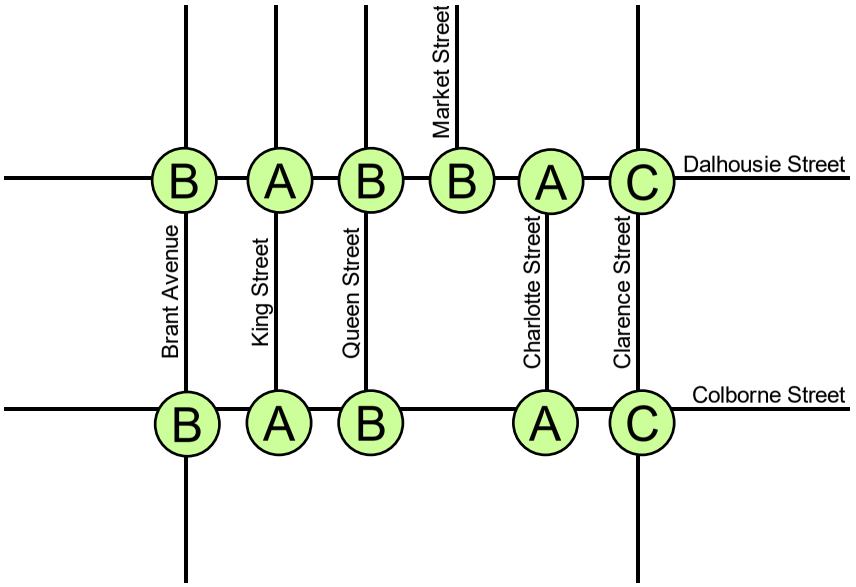
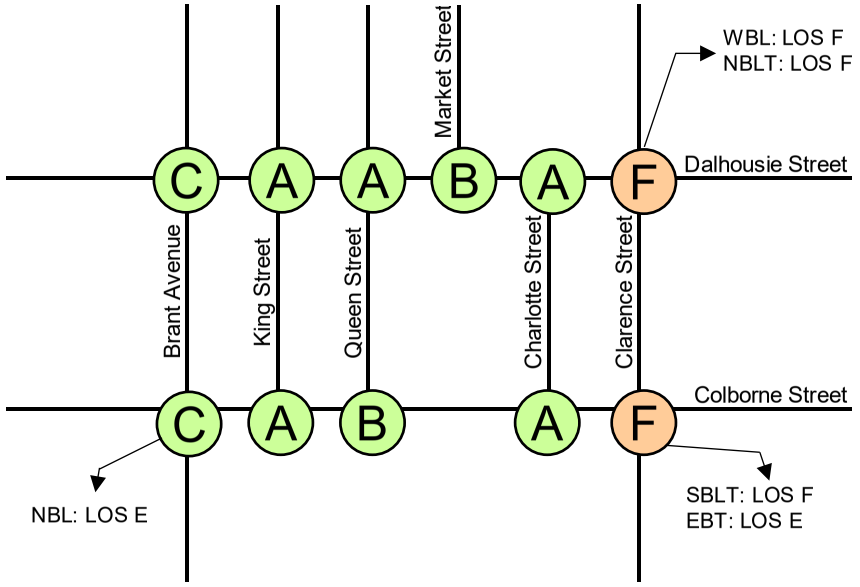
Weekday AM Peak Hour



Weekday PM Peak Hour



2051 (One-Way) Weekday Peak Hour LOS

5.2 Two-Way Traffic Volumes (2051)

5.2.1 Lane Configuration Assumptions

The two-way alternative is based on a minimal provision of left turn lanes at unsignalized intersection in an effort to minimize the need to eliminate on-street parking and to maximize the pedestrian realm. The conversion of Colborne Street and Dalhousie Street to two-way operation is based on the existing roadway geometrics and makes use of lanes already present on the roadway with only re-stripping of the lane markings to include a lane in the opposite direction.

The basic cross-section of this alternative would result in most sections of Colborne Street having one eastbound travel lane and one westbound travel lane with additional eastbound turning lanes at some major intersections. Dalhousie Street would have primarily one travel lane in each direction west of Clarence Street and two westbound and one eastbound travel lane east of Clarence Street, with turning lanes at key intersections.

With respect to the intersection of Colborne Street and Brant Avenue, conversion of this intersection to two-way operation would likely result in a skewed alignment for westbound traffic flow through the intersection. There would likely be property impacts to achieve an acceptable east-west alignment of Colborne Street if the current configuration for the east leg is maintained. Alternatively, to maintain a relatively straight alignment through the intersection, consideration to eliminate the channelized southbound right turn lane and narrowing of the east leg to a shared through/right turn lane while maintaining dual eastbound left turn lanes is expected to be required. While this modification would have somewhat of an impact on operations, removal of the channelization and narrowing the crossing distance is seen as beneficial to improve pedestrian crossings at this intersection.

5.2.2 Operational Assessment

Table 5.2 summarizes the lane configuration assumptions, the AM and PM LOS, the critical movements v/c ratio, and the total delay for the 2051 two-way operational analysis. **Figure 5.2** graphically display the results and note:

- Similar to the one-way scenario, the Clarence Street corridor is projected to operate with high levels of delay not only for the weekday PM peak hour but also for the Weekday AM peak hour. In addition, an increased delay is projected at the Colborne Street and Brant Avenue intersection for several movements during the Weekday PM peak hour. This results from increased vehicle demand, given the reduction in lane capacity that is expected to be required to achieve an appropriate alignment to facilitate two-way operation at the intersection.

TABLE 5.2: 2051 (TWO-WAY) TRAFFIC OPERATIONS

6 One-Way vs Two-Way

Decisions regarding one-way versus two-way streets need to be context sensitive and value-based, having regard for the shared community vision, planned road functions, and competing interests for the valued and often constrained right-of-way (ROW) of any given street.

6.1 Advantages and Disadvantages

6.1.1 Two-Way Streets

- Decreased vehicle distances travelled: By eliminating indirect routes, the distances that vehicles are required to travel to reach a destination may be slightly lower (i.e., eliminate driving around the block).
  - Counterpoint: Similar behaviour can occur as drivers search for on-street parking spaces immediately adjacent to their destination; major parking facilities often provide multiple access/egress points efficiently serving a one-way street network.
- Slower travel speeds: With the additional friction resulting from two-way traffic operation, mid-block speeds are typically lower on two-way streets.
  - Counterpoint: Intersections are the critical points within the corridor, and any resulting congestion at intersections could adversely impact transit service reliability and the ability of emergency vehicles to respond to calls.
- Improved pedestrian (and cyclist) safety: With the foregoing lower travel speeds, pedestrians on the sidewalk (and cyclists within the travelled asphalt) may be considered safer.
  - Counterpoint: Appropriately designed sidewalks and on-road cycling facilities on one-way streets can help to enhance the pedestrian and cycling environment.

6.1.2 One-Way Streets

From a transportation planning perspective, the advantages of one-way streets are:

- Narrow street cross-section: A street can accommodate relatively high traffic volumes with only two travel lanes, given that turning movements can happen from one lane or the other. By comparison, a two-way street will need a wider, three (3) lane cross-section to accommodate a turning lane (otherwise traffic would come to standstill waiting for a single vehicle to turn). This wider cross-section would occur at intersections where pedestrian crosswalks would therefore be lengthened in the two-way scenario.
- Improved signal coordination: Coordination of traffic signals is more easily attained within an area such as downtown environments where signals by necessity are closely spaced (i.e., short blocks). This results in improved traffic and bus transit flow with fewer stops, less idling, and lower emissions. Note that signal timing parameters (i.e., offsets) can be used to regulate travel speeds.
  - Counterpoint: Higher travel speeds for vehicles are the result of coordinated traffic signals, which is not considered conducive to a welcoming pedestrian environment and safe cycling.
- Increased capacity: The capacity of one-way streets can be approximately 10% to 20% greater than that of two-way streets. Increased capacity can translate into fewer lanes and fewer through streets within a one-way grid system, or alternatively, the option to reprogram any surplus capacity/ space for other purposes (i.e., dedicated parking lanes, bicycle lanes, wider sidewalks).
  - Counterpoint: None.
- Reduced congestion and delay: Congestion and delay is reduced for all modes, including pedestrians, vehicles and transit. Delay is often reduced as the cycle length can be much shorter with one-way streets. The extra phases to accommodate left-turn movements are unnecessary with one- way streets.
  - Counterpoint: The one-way system forces drivers to follow out of direction routes, and this recirculation results in an increase in traffic volume on a given segment or intersection within a one-way system.

- Improved pedestrian safety at intersections: The pedestrian has fewer directions to be concerned about at intersections involving one-way streets, and drivers have fewer potential conflicts to process (and can give more attention to pedestrian safety). Safety studies conducted from the 1930's to the 1970's of before and after conditions (as cities switched from two-way to one-way) consistently found that one-way streets had 10% to 20% lower accident rates than when previously two-way, and pedestrian accidents dropped by 30% to 60%.
  - Counterpoint: At intersections of two-streets that are each two-way, pedestrians have an expectation of potential vehicular conflicts with their path as they cross the intersection. These expectations can be different at the intersection of one-way streets, which may create a less safe pedestrian environment.

6.2 Operations

The analyses of the traffic conditions found that the peak period level of service conditions at the downtown street intersections are generally at satisfactory levels. This is particularly the case within the downtown area where most intersections operate at level of service A or B.

The intersections projected to experience some congestion are generally at the centre of the downtown core (i.e., Clarence Street) under both the one-way and two-way scenarios.

A widening of Clarence Street would result in significant property impacts and would be constrained by the railway spur line on the east side (limiting widening options to the west side). The Veterans Memorial Parkway partial extension (to Murray Street) provides an opportunity for an alternative route out of downtown via Murray Street. A partial extension of the Veterans Memorial Parkway could be considered beyond 2051 to address potential long-term issues and should be protected for as an alternative to Clarence Street.

In addition, the two-way scenario is also expected to create some additional capacity constraints at the intersection of Colborne Steet and Brant Avenue given modifications to the east leg are required to achieve a straight alignment through the intersection.

Overall, the one-way street traffic operations have fewer turning movement conflicts at intersections and the traffic control along a one-way street can be coordinated to maintain smooth, uninterrupted flow of traffic through a number of intersections. In summary, the one-way scenario offers the least amount of delay and travel time as a result of

limited conflicts for turning vehicles at intersections as there is no traffic travelling in the opposite direction to delay either a left turn or right turn movement.

6.3 Balanced Network

The primary intent of the preferred streetscaping alternative is to improve walkability and accessibility for all transportation modes. One of the main objectives of the preferred alternative is to create a complete street that will capitalize on the walkability and pedestrian capacity of downtown, animate these streets and become a place-making destination. As the vision for each street needs to be considered, a review of the options and what opportunities a one-way vs two-way system provides in perspective of this vision.

Although it seems to be a commonly held view that converting the high-speed and high-capacity one-way downtown streets to two-way could be necessary for a downtown revitalization program, there are advantages to bringing together different types of activities within a relatively dense and diversified environment. There are also advantages to using multitudinous strategies to achieve an objective with several interrelated factors.

As the downtown streets are provided with a narrow right-of-way with limited opportunity to expand, there are many competing interests for space, including sidewalks, bus stops/shelters, landscaping, public art, bicycle parking, vendor boxes, streetlights, fire hydrants, on-street parking, and travel lanes. Given the intensity of use and the increase in intensity that is envisioned with the Streetscape investment, decisions regarding the allocation of space are anticipated to become more complex

There is considerable literature available on the opportunities and constraints of converting existing one-way streets to two-way operation, and depending on one's perspective, convincing arguments can be made for the merits of each system. The real question as applied to Brantford is how the narrow rights-of-way best can be utilized to function as complete street. The following considerations are appropriate for downtown Brantford streets:

- One-way streets generally promote efficient vehicle travel by accommodating heavy traffic volumes and improved opportunity for traffic signal coordination between intersections. They offer an opportunity to reallocate more space towards sidewalks and/or cycling facilities, allowing for development of complete streets.

- Benefits associated with one-way streets include decreased congestion, associated reduction in air pollution, reduced time delays for all modes, reduced pedestrian/cyclist conflicts with turning vehicles, increased safety at intersection crossings.
- Two-way streets generally promote increased accessibility to local destinations, desirable slower traffic speeds, and more comfortable street environment for pedestrians and cyclists. They benefit street-oriented land uses at grade level, provide scenic views from both directions and tend to calm down traffic speeds.
- The potential conversion to two-way operation of Colborne Street and Dalhousie Street would place considerable additional pressure on Clarence Street and Brant Avenue to accommodate the diverted traffic.

Balancing the competing interests for space is always the first challenge when designing complete streets. In downtown Brantford, this competition is fierce due to the volume of travel in all modes that must be accommodated within municipal street rights-of-way that are incredibly narrow. As a result, it is sensible to create street design solutions that can fit within the narrow right-of-way that covers most of downtown Brantford.

6.4 Pedestrian Safety

Perhaps the greatest consideration between one-way and two-way conversions is pedestrian safety. The speed and pattern of vehicular traffic on the street significantly impact the level of protection afforded to non-vehicular street users. This group of users can be pedestrians, bicyclists, and other non-motorists.

Pedestrian safety in downtown commercial streets is paramount because in most cases, a downtown motorist's destination is some place to park the car, namely a garage, lot or on-street parking space; upon parking, the motorist leaves the vehicle as a pedestrian to access the final destination.

Both sides of the one-way to two-way debate accept the importance of pedestrian safety but there is not an agreement as to which way of travel is actually safer as pedestrian safety may depend on characteristics that can only be determined on a case-by-case basis. There are several benefits of two-way streets that positively affect pedestrian safety and pedestrian experience; a relatively new criterion for successful downtowns.

6.5 Experience from Other Cities

There are many cities in Canada and the United States that have been converting their one-way streets to two-way. The rationale for such conversions has tended to focus on creating a pedestrian friendly environment, calming traffic, attracting new neighbourhood businesses, and reducing the navigation confusion for visitors. Below are two somewhat recent examples of one-way conversions in Ontario, although there is no quantitative evidence of traffic impacts that could be identified and/or provided.

- Hamilton, ON: Hamilton is infamous for having mainly one-way streets throughout its downtown core. Conversion back to two-way streets began in 2002, including John Street and James Street (considered two main north-south arterial roads). The conversion featured sidewalks, on-street parking (on both sides), two travel lanes, but no dedicated cycling lane.
- St. Catharines, ON: The one-way commercial spine of downtown St. Catharines opened up a portion of the street to two-way traffic in 2010. The converted street features one travel lane per direction, on-street parking (one side only), sidewalks, but no dedicated cycling lane.

It also clear in reviewing literature that there are many examples of North American cities that offer an attractive pedestrian environment even with the presence of one-way street networks.

- New York City, NY features a road network that is almost exclusively one-way streets, and it is considered an extremely vibrant pedestrian environment.
- Montreal, QC, Rue Sainte Catherine and Boulevard de Maisonneuve and others are one-way streets and are considered very successful commercial streets within the downtown core of the city.

In both of these cases, the width of the road, width of sidewalks, presence of on-street parking, access to public transit and most importantly, built form of the buildings on the street, each impact street life far greater than one-way traffic.

6.6 Downtown Brantford

For most of the one-way streets in the downtown Brantford, the identified cross sections generally consist of two travel lanes and sidewalks on both sides. Auxiliary turn lanes are seldom provided at intersection because they are not essential given the one-way operation (i.e., no conflicting movement in the opposite direction, and turning movements accommodated from one of the two available lanes at intersections). None of the existing one-way streets currently have dedicated, high quality, on-road cycling facilities.

With a limited ROW, and when striving for sidewalks of appropriate width particularly at intersections, it is not possible to have road cross-sections including three lanes of traffic and on-street cycling facilities. It is also concluded that in the downtown environment, for a two-way street, a turn lane would be preferred at most intersections to improve traffic operations.

This is to provide for a basic level of vehicle mobility, but also to enable the movement of emergency services vehicles through a congested or blocked intersection (such as during an accident), as well as transit vehicles and general traffic. This results in a three-lane cross-section at intersections, for two-way streets. However, for one-way streets, it may be appropriate to have only a two-lane cross-section at intersections. If one of the lanes is blocked either by a turning vehicle or an accident, there is an available lane for vehicles to “slip around” the blocked lane, and keep traffic flowing, including buses.

The conclusion is that, given the narrow right of way along Colborne Street and Dalhousie Street where a dedicated cycling facility is to be provided and sidewalks are to be of appropriate width, this can most readily be accomplished in a one-way vehicular arrangement. However, if dedicated cycling is not a requirement and shared use vehicle/cycling lanes are appropriate, then a two-way, two-lane (three-lane at intersections), with ample pedestrian sidewalk space can be accommodated.

6.7 Preferred Arrangement

The foregoing assessment indicates there are valid arguments for both maintaining an existing one-way street network in Downtown Brantford, and conversely, converting one-way operation to two-way operation.

There are many examples of one-way street conversions in other cities, typically on roads carrying modest traffic volumes, leading to improved commercial and pedestrian environments. Similarly, many

examples of successful commercial and pedestrian environments within existing one-way street corridors, including New York City and Montreal. These successes demonstrate that there are likely elements at play other than the direction of traffic flow that characterizes a thriving street, such as the width of the roadway, number of travel lanes, width of sidewalks, presence of on-street parking, cycling facilities, access to public transit, the quality of built form and streetscaping along the street, and market conditions.

In the documented instances of one-way street conversions completed in other cities, the desired outcome for a community was often established based on urban planning principles (i.e., better pedestrian environment, improved retail, commercial viability, etc.). In most cases, the outcome appears to have been achieved from anecdotal evidence only. However, there is a surprising lack of quantitative evidence demonstrating the effects of the conversion from one-way to two-way operation. Pedestrian safety appears to be the most-cited metric of before-and-after studies, with many studies claiming a one-way street system was safer. In short, the technical findings were undoubtedly varied and non-conclusive. Traditional traffic performance measures, such as the impact on traffic volume, intersection performance, or travel time/delay, were not evident in the literature. Therefore it was not possible to learn much from the experiences of previous one-way street conversions in this regard.

In downtown Brantford's case, the primary one-way street network is considered somewhat unique given the connectivity the subject streets provide to key elements of the region's transportation infrastructure and bridge crossings of rivers. It is also worth noting that the downtown streets with the most mixed and street-oriented land use and high and sustained pedestrian activity are two-way streets. More importantly, the narrow ROW reality of downtown Brantford streets creates added pressure on the roads to operate as efficiently as possible for all modes. Since the vision for the downtown is to pursue streets that can provide wider sidewalks and on-street cycling facilities, as well as basic functionality for vehicles and buses, this tends to balance the scales towards one-way operation, provided the narrow ROW can be re-arranged accordingly.

7 Preferred Alternative

Alternative 4 and Alternative 5 both consist of maintain a one-way configuration with incorporating active transportation facilities. Differences between these alternatives is that Alternative 4 provides for bi-directional cycling facilities without an increase in the pedestrian realm whereas Alternative 5 consists of a single cycling lane with an increase in the pedestrian realm. To further evaluate each alternative, a number of additional criteria have been considered.

7.1 Additional Impacts

7.1.1 Road Safety

From a safety perspective, maintaining the one-way configuration is expected to:

- Improve cyclist safety and comfort by providing dedicated bicycle lanes and removing the potential conflicts between cyclists and vehicle parking;
- Have fewer turning movement conflicts at intersections; and
- Traffic control along a one-way street can be coordinated to maintain smooth, uninterrupted flow of traffic through a number of intersections.

Potential safety conflicts are still possible at:

- Intersections between cyclists and turning vehicles;
- The more efficient traffic movement along a one-way corridor could contribute to higher traffic speed
- Transit stops between cyclists and stopped transit vehicles and between cyclists with pedestrians getting on/off transit.

Overall Alternative 4 and 5 have similar cross-sections, however Alternative 4 provides for bi-directional cycling facilities which could led to increased collision potential at minor intersections as drivers can forget to check the other direction especially along a one-way configuration. Alternative 5 is preferred.

7.1.2 Emergency Vehicles

As Colborne Street and Dalhousie Street currently operate in a one-way configuration, emergency response delays are not expected to incur or degrade from current service levels. Alternative 4 and 5 perform similarly from an emergency vehicle perspective.

However, further consultation with Brantford Fire Service (BFS) and Emergency Medical Service (EMS) will need to further be undertaken to identify any potential concerns with the preferred cross-section.

7.1.3 On-Street Parking

Both alternatives results in a loss of 84 on-street parking spaces. Downtown Brantford contains well over 1,600 parking spaces in various offsite parking garage and lots can readily absorb these losses as there are 380 vacant spaces within these lots during peak periods.

With a fair amount of off-site parking located within the sub-study area and within walking distance, the need to provide on-street parking is not a significant requirement. Alternative 5 is preferred over Alternative 4 as it results in wider sidewalks and a more accessible, walkable pedestrian-friendly area.

7.1.4 Loading and Unloading

With two lanes on each street with existing one-way system loading activity takes place on one lane while the other lane remains open to traffic.

Alternative 4 and 5 perform similarly from a loading and unloading perspective.

7.1.5 Traffic Infiltration

Modelling results support the notion that localized traffic infiltration is not projected to occur to any significant degree with either alternative. This is further supported by the forecast operational analyses which show the surrounding local and collector roads and intersections performing well.

Alternative 4 and 5 perform similarly from a traffic infiltration perspective.

7.1.6 Transportation Demand Management

Transportation Demand Management (TDM) programs include policies that reduce car travel and reduce peak period travel in general, including encouraging flexible work hours, working with commercial building owners to provide cycling friendly infrastructure such as bike racks and shower facilities, a Smart Commute association including car pooling programs and incentives as well car share service should be further explored.

Alternative 4 provides for better cycling facilities as cyclists can navigate more quickly through the bi-directional cycling lanes; however Alternative 5 provides for an increased pedestrian realm to improve the walking experience.

Overall, as the intent of TDM is to encourage active transportation, both Alternative 4 and 5 encourage sustainable travel.

Additionally, TDM programs in the sub-area should continue and be encouraged through policy enforcement and implementation to decrease peak hour vehicle demand. In any event, a follow-up traffic study to the Environmental Assessment should be conducted to investigate the aforementioned options.

7.2 Preferred Alternative

Alternative 5 is preferred over Alternative 4 as this option is better suited to improving and providing increased protection for active transportation users. This alternative further encourages TDM within the study area by significantly focusing on active travel modes.

7.3 Preferred Lane Arrangement

The lane configuration of the preferred scenario is summarized in the following sections.

7.3.1 Colborne Street at Brant Avenue

Preferred lane configuration consists of dual left turn lanes for the eastbound approach and separate left turn lanes for the northbound and southbound approaches. From a safety perspective, removal of the southbound channelization could reduce conflicts between vehicles and pedestrians. However, given the large volumes of southbound right turning vehicles, removal of the channelization would likely have an impact on operations along Brant Avenue. Instead, the installation of a Pedestrian Crossover (PXO) would provide for a controlled crossing opportunity for pedestrians while still maintaining capacity to serve the high volume of southbound right turns.

Forecast operations at this intersection under the 2051 horizon is noted to be acceptable (LOS C) with optimized traffic control signals.

7.3.2 Colborne Street at King Street

Preferred lane configuration consists of a shared left/through lane and separate through lane for the eastbound approach. The southbound approach to consist of a single left turn lane. Stop control is provided for the southbound approach. A cycle lane on the north side is proposed as well as an increased pedestrian realm to improve the active transportation network.

Forecast operations at this intersection under the 2051 horizon is noted to be acceptable (LOS A) with stop control for the southbound approach.

7.3.3 Colborne Street at Queen Street

Preferred lane configuration consists of a shared left/through lane and separate through lane for the eastbound approach. The southbound approach to consist of a single left turn lane. A cycle lane on the north side is proposed as well as an increased pedestrian realm to improve the active transportation network.

Forecast operations at this intersection under the 2051 horizon is noted to be acceptable (LOS B) with stop control for the southbound approach.

7.3.4 Colborne Street at Charlotte Street

Preferred lane configuration consists of a shared left/through lane and separate through lane for the eastbound approach. The southbound approach to consist of a single left turn lane. A cycle lane on the north side is proposed as well as an increased pedestrian realm to improve the active transportation network.

Forecast operations at this intersection under the 2051 horizon is noted to be acceptable (LOS A) with stop control for the southbound approach.

7.3.5 Colborne Street at Clarence Street

Preferred lane configuration consists of a separate left turn lane for the eastbound and southbound approaches. A separate right turn lane be provided for the eastbound and northbound approaches.

Forecast operations at this intersection under the 2051 horizon is noted to be acceptable (LOS C) with optimized traffic control signals.

7.3.6 Dalhousie Street at Clarence Street

Preferred lane configuration consists of a separate left turn lane and right turn lane for the westbound approach. The northbound approaches will operate with a separated left turn lane, separate through lane and shared right/through lane.

Forecast operations at this intersection under the 2051 horizon is noted to be satisfactory (LOS D) with optimized traffic control signals.

7.3.7 Dalhousie Street at Charlotte Street

Preferred lane configuration consists of a shared left/through lane and shared right/through lane for the westbound approach. The southbound approach to consist of a single through/right turn lane while the northbound approach to consist of a shared through/left turn lane. Stop control is provided for the southbound approach. A cycle lanes on the south side is proposed and an increased pedestrian realm.

Forecast operations at this intersection under the 2051 horizon is noted to be acceptable (LOS A) with stop control for the southbound and northbound approach.

7.3.8 Dalhousie Street at Market Street

Preferred lane configuration consists of a shared right/through lane and separate through lane for the westbound approach. The southbound approach to consist of a single right turn lane. A cycle lanes on the south side is proposed and an increased pedestrian realm.

Forecast operations at this intersection under the 2051 horizon is noted to be acceptable (LOS B) with optimized traffic control signals.

7.3.9 Dalhousie Street at Queen Street

Preferred lane configuration consists of a shared through/left turn lane and shared through/right turn lane for the westbound approach. The southbound approach to consist of a separate right turn lane and through lane while the northbound approach to consist of a shared through/left turn lane. A cycle lane on the south side is proposed and an increased pedestrian realm.

Forecast operations at this intersection under the 2051 horizon is noted to be acceptable (LOS B) with optimized traffic control signals.

7.3.10 Dalhousie Street at King Street

The preferred lane configuration consists of a shared left/through lane and a shared through/right turn lane for the westbound approach. The southbound approach consists of a single through/right turn lane while the northbound approach consists of a shared through/left turn lane. A cycle lane on the south side and an increased pedestrian realm are proposed.

Forecast operations at this intersection under the 2051 horizon are considered acceptable (LOS B) with optimized traffic control signals.

7.3.11 Dalhousie Street at Brant Avenue

The preferred lane configuration consists of dual left turn lanes for the westbound approach. From a safety perspective, the projected volumes indicate a separate westbound right turn lane is not required; instead, a shared through/right turn lane will provide adequate operations while reducing the crossing distance for pedestrians.

Forecast operations at this intersection under the 2051 horizon is noted to be acceptable (LOS C) with optimized traffic control signals.

7.4 Operations

A sensitivity analysis has been undertaken for the preferred lane configuration. **Table 7.1** summarizes the lane configuration assumptions, the AM and PM LOS, the critical movements v/c ratio, and the total delay for the 2051 two-way operational analysis. **Figure 7.3** graphically displays the results and note:

- With the addition of left-turn lanes along the Clarence Street corridor, the intersections with Colborne Street and Dalhousie Street operate with improved operations during the weekday peak hours.

TABLE 7.1: 2051 PREFERRED TRAFFIC OPERATIONS

2051 (Preferred) Weekday Peak Hour LOS

7.5 Queen Street Closure

As the study area consists of a gride network with short blocks, there is an opportunity to modify to transform some of the street network as a predominately active transportation corridor.

Pedestrian-only streets prioritize people and are typically most appropriate in corridors with commercial activity on both edges of the road. They are strategically selected streets where pedestrian volume is high and vehicular traffic is restricted. These streets offer opportunities for diverse activities such as shopping or sitting, dining or dawdling, promenading or performing. When placed, designed, and maintained well, pedestrian-only streets become a destination, resulting in economic benefits for adjacent businesses.

These streets are not new to Brantford, as Market Street between Colborne Street and Dalhousie Street currently operates in this manner. Based on the pedestrian “heat maps” in **Figure 5.2**, Queen Street would be a suitable candidate for a pedestrian-only street as there is a high volume of pedestrians along Queen Street at both the Colborne Street and Dalhousie Street intersections.

With the closure of Queen Street, traffic volumes are expected to re-route to the adjacent corridor of King Street. To determine the impacts, the reassignment of trips has been modelled to determine if any traffic operations impacts are projected. **Table 7.2** the results of the analysis for the 2051 horizon. The following is noted:

- With the addition of re-routed traffic to the intersections of Colborne Street at King Street and Dalhousie Street at King Street with the closure of Queen Street, the intersections are projected to operate with acceptable operations during the weekday peak hours.

TABLE 7.2: 2051 QUEEN CLOSED TRAFFIC OPERATIONS

		AM	PM	LOS - V/C - Delay			AM	PM	LOS - V/C - Delay
2 - Colborne Street at King Street		A	A		12 - Dalhousie Street at King Street		A	A	

8 Conclusions

Colborne Street and Dalhousie Street has frequently been discussed as potential street to convert from one-way to two-way. Decisions regarding one-way versus two-way streets need to be context-sensitive and value-based, having regard for the shared community vision, planned road functions, and competing interests for the valued and often constrained right-of-way (ROW) of any given street.

Operations

The 2051 forecast traffic conditions under the one-way and two-way scenarios indicate that the peak period level of service conditions at the downtown street intersections are generally satisfactory. This is particularly the case within the downtown area, where most intersections operate at a level of service A or B. The intersections projected to experience some congestion are generally at the centre of the downtown core (i.e., Clarence Street) under both the one-way and two-way scenarios.

A widening of Clarence Street would result in significant property impacts and would be constrained by the railway spur line on the east side (limiting widening options to the west side). The Veterans Memorial Parkway partial extension (to Murray Street) provides an opportunity for an alternative route out of downtown via Murray Street. A partial extension of the Veterans Memorial Parkway could be considered beyond 2051 to address potential long-term issues and should be protected for as an alternative to Clarence Street.

In addition, the two-way scenario is also expected to create some additional capacity constraints at the intersection of Colborne Steet and Brant Avenue given modifications to the east leg are required to achieve a straight alignment through the intersection.

In summary, the one-way scenario offers the least amount of delay and travel time as a result of limited conflicts for turning vehicles at intersections as there is no traffic travelling in the opposite direction to delay either a left turn or right turn movement.

Complete Street

As the primary intent of the preferred streetscaping alternative is to improve walkability and accessibility for all transportation modes, one of the main objectives in determining the preferred alternative is to create a complete street. Although it seems to be a commonly held view that converting the high-speed and high-capacity one-way

downtown streets to two-way could be necessary for a downtown revitalization program, there are advantages to bringing together different types of activities within a relatively dense and diversified environment. There are also advantages to using multitudinous strategies to achieve an objective with several interrelated factors.

As the downtown streets are provided with a narrow right-of-way with limited opportunity to expand, there are many competing interests for space, including sidewalks, bus stops/shelters, landscaping, public art, bicycle parking, vendor boxes, streetlights, fire hydrants, on-street parking, and travel lanes. Given the intensity of use and the increase in intensity envisioned with the Streetscape investment, decisions regarding space allocation are anticipated to become more complex.

Balancing the competing interests for space is always the number one challenge when designing complete streets. In downtown Brantford, this competition is fierce due to the volume of travel in all modes that must be accommodated within municipal street rights-of-way that are incredibly narrow. As a result, it is sensible to create street design solutions that can fit within the narrow right-of-way that cover most of downtown Brantford.

Pedestrian Safety

Pedestrian safety in downtown commercial streets is paramount because in most cases, a downtown motorist's destination is some place to park the car, namely a garage, lot or on-street parking space; upon parking, the motorist leaves the vehicle as a pedestrian to access the final destination.

Both sides of the one-way to two-way debate accept the importance of pedestrian safety but there is not an agreement as to which way of travel is actually safer as pedestrian safety may depend on characteristics that can only be determined on a case-by-case basis. There are several benefits of two-way streets that positively affect pedestrian safety and pedestrian experience; a relatively new criterion for successful downtowns.

Preferred Arrangement

The foregoing assessment indicates there are valid arguments for both maintaining an existing one-way street network in Downtown Brantford, and conversely, converting one-way operation to two-way operation.

In downtown Brantford's case, the primary one-way street network is considered somewhat unique given the connectivity the subject streets

provide to critical elements of the region's transportation infrastructure and bridge crossings of rivers. It is also worth noting that the downtown streets with the most mixed and street-oriented land use and high and sustained pedestrian activity are two-way streets. More importantly, the narrow ROW reality of downtown Brantford streets creates added pressure on the roads to operate as efficiently as possible for all modes. Since the vision for the downtown is to pursue avenues that can provide wider sidewalks and on-street cycling facilities, as well as basic functionality for vehicles and buses, this tends to balance the scales towards one-way operation, provided the narrow ROW can be re-arranged accordingly.

Preferred Alternative

As the one-way operation is seen as the beneficial arrangement in meeting the overall goals and intent of the Streetscaping alternative, Alternatives 4 and 5 were determined to meet this criteria for further consideration. A comparison of these alternative concluded that Alternative 5 is preferred over Alternative 4 as it is better suited towards improving road safety and enhancing the overall pedestrian realm.

To ensure that the response times of emergency vehicles are not impacted negatively by the proposed changes to Colborne Street and Dalhousie Street, it is recommended that City of Brantford Transportation Services work with Brantford Fire Services to further refine the pre-emption along the Colborne Street and Dalhousie Street corridor. In addition, further consultation with Brantford Fire Services is recommended during detailed design.

To improve the potential safety hazards within the sub study-area, the implementation of a blanket 40 kilometres posted speed limit along Colborne Street and Dalhousie Street is preferred. Furthermore, improved sidewalks (i.e., wider with limited to no obstructions) and cycling facilities will need to be incorporated. Ultimately, the preferred design and streetscape design should support these recommendations.

Other improvements that may need to be considered in the final design could include bike signals, pedestrian only phases (reserved for intersections with high pedestrian volumes) and pedestrian leading green time to provide pedestrians with an advance opportunity to cross before vehicles are allowed to proceed right.

Additionally, the measures identified are further recommended for consideration:

- The intersection of Dalhousie Street and Bridge Street be modified to only one-way traffic in the northbound direction to reduce the number of potential conflicts with westbound through traffic.
- To mitigate the number of active transportation collisions along Colborne Street between the Market Street IPS and Clarence Street, an additional controlled crossing be considered.

Intersection Summary
Area Type: Other
Cycle Length: 120
Actuated Cycle Length: 120
Offset: 0 (0%), Referenced to phase 2:EBTL, Start of Green
Natural Cycle: 150
Control Type: Pretimed
Maximum v/c Ratio: 1.77
Intersection Signal Delay: 163.8 Intersection LOS: F
Intersection Capacity Utilization 149.0% ICU Level of Service H
Analysis Period (min) 15
~ Volume exceeds capacity, queue is theoretically infinite.
Queue shown is maximum after two cycles.
95th percentile volume exceeds capacity, queue may be longer.
Queue shown is maximum after two cycles.
m Volume for 95th percentile queue is metered by upstream signal.

Splits and Phases: 6: Clarence Street & Colborne

~ Volume exceeds capacity, queue is theoretically infinite.
Queue shown is maximum after two cycles.
95th percentile volume exceeds capacity, queue may be longer.
Queue shown is maximum after two cycles.

~ Volume exceeds capacity, queue is theoretically infinite.
Queue shown is maximum after two cycles.
95th percentile volume exceeds capacity, queue may be longer.
Queue shown is maximum after two cycles.
m Volume for 95th percentile queue is metered by upstream signal.

~ Volume exceeds capacity, queue is theoretically infinite.
Queue shown is maximum after two cycles.
95th percentile volume exceeds capacity, queue may be longer.
Queue shown is maximum after two cycles.
m Volume for 95th percentile queue is metered by upstream signal.

Intersection Capacity Utilization 156.1% ICU Level of Service H
Analysis Period (min) 15

~ Volume exceeds capacity, queue is theoretically infinite.
Queue shown is maximum after two cycles.
95th percentile volume exceeds capacity, queue may be longer.
Queue shown is maximum after two cycles.
m Volume for 95th percentile queue is metered by upstream signal.

~ Volume exceeds capacity, queue is theoretically infinite.
Queue shown is maximum after two cycles.
95th percentile volume exceeds capacity, queue may be longer.
Queue shown is maximum after two cycles.
m Volume for 95th percentile queue is metered by upstream signal.
